2019 Annual Report of Hydrogeologic Conditions Water Requirements, Supplies, and Disposition

Santa Maria Valley Management Area

April 29, 2020

prepared by

PREAMBLE

This report provides an assessment of hydrogeologic conditions and accounting of water used in the Santa Maria Valley Management Area (SMVMA) in 2019 in accordance with provisions of the Stipulation entered in 2008 by the Superior Court of the State of California, County of Santa Clara (the Court). The Stipulation specifies that the Twitchell Management Authority (TMA) administer relevant provisions of the Stipulation regarding the SMVMA; further, it specifies that the SMVMA Engineer (the Engineer) compile the results of the annual assessment and accounting into a report for submittal to the Court.

The guidelines for this report are as approved by the Court, which holds continuing jurisdiction over the Santa Maria Groundwater Basin regarding the disposition of groundwater. The report is compiled from information derived from the monitoring program for the SMVMA. Per the Stipulation, the program collects information, including groundwater level and groundwater quality data, sufficient to assess groundwater conditions. The program also collects information to account for water use in the SMVMA, including the demand, supply, and disposition.

Based on the annual assessment of hydrogeologic conditions and accounting of water used in the SMVMA, the Stipulation requires a determination be made by the Engineer as to whether a condition of severe water shortage exists in the SMVMA. The Stipulation delineates four specific criteria that, when all are met in any given year, define a condition of severe water shortage; those four criteria are:

- chronic decline in groundwater levels (over period of not less than 5 years);
- groundwater levels below lowest recorded levels;
- groundwater level decline not caused by drought; and
- material increase in groundwater use during the five-year period.

Should a condition of severe water shortage exist, the Stipulation directs the Engineer to provide findings and recommendations as part of its annual report to alleviate such a condition or the associated adverse effects.

1 INTRODUCTION

This annual report of conditions in the Santa Maria Valley Management Area, for calendar year 2019, has been prepared to meet the reporting conditions of the June 30, 2005, Stipulation entered by the Superior Court of the State of California, County of Santa Clara, in the Santa Maria Valley Groundwater Basin litigation. The Stipulation divided the overall Santa Maria Valley Groundwater Basin into three management areas, the largest of which overlies the main Santa Maria Valley (the Santa Maria Valley Management Area, or SMVMA) and is the subject of this report. The other two management areas, the Nipomo Mesa Management Area (NMMA) and the Northern Cities Management Area, are addressed in separate annual reports prepared by others.

The Stipulation, approved and implemented in 2008, specifies that monitoring shall be sufficient to determine groundwater conditions, land and water uses, sources of water supply, and the disposition of all water supplies in the Basin. Annual Reports for the SMVMA are to summarize the results of the monitoring and include an analysis of the relationship between projected water demand and supply. The Stipulation was preserved in the California Court of Appeal (Sixth Appellate District) Decision of November 21, 2012, and in the Superior Court of the State of California (County of Santa Clara) Final Judgment of April 23, 2014. Thus, the Physical Solution criteria for monitoring and managing groundwater in the basin remain.

In accordance with the Stipulation, this report on the SMVMA provides a description of the physical setting and briefly describes previous studies conducted in the groundwater basin, including the long-term monitoring program developed for the SMVMA. As reported herein, the Twitchell Management Authority (TMA) commissioned the preparation of a monitoring program for the SMVMA in 2008, and its complete implementation is expected to provide the data with which to fully assess future conditions. This report describes hydrogeologic conditions in the management area historically and through 2019, including groundwater conditions, Twitchell Reservoir operations, and hydrologic and climatic conditions. As with all previous annual reports (commencing in 2008), the water requirements and supplies for agricultural and municipal uses are accounted, as are the components of water disposition in the SMVMA. Conclusions drawn regarding water resource conditions are discussed, including any finding of severe water shortage, which is concluded to not be the case through 2019. Finally, recommendations are provided regarding the enhancement of groundwater recharge and expansion of the SMVMA monitoring program.

1.1. Physical Setting

The Santa Maria Valley Management Area (SMVMA) includes approximately 175 square miles of the Santa Maria Valley Groundwater Basin in northern Santa Barbara and southern San Luis Obispo Counties, as shown by the location map of the area (**Figure 1.1-1**). The SMVMA encompasses the contiguous area of the Santa Maria Valley, Sisquoc plain, and Orcutt upland, and is primarily comprised of agricultural land and areas of native vegetation, as well as the urban areas of Santa Maria, Guadalupe, Orcutt, Sisquoc, and several small developments. Surrounding the SMVMA are the Casmalia and Solomon Hills to the south, the San Rafael Mountains to the southeast, the Sierra Madre Mountains to

the east and northeast, the Nipomo Mesa to the north, and the Pacific Ocean to the west. The main stream is the Santa Maria River, which generally flanks the northern part of the Santa Maria Valley; other streams include portions of the Cuyama River, Sisquoc River and tributaries, and Orcutt Creek.

1.2. Previous Studies

The first overall study of hydrogeologic conditions in the Santa Maria Valley described the general geology, as well as groundwater levels and quality, agricultural water requirements, and groundwater and surface water supplies as of 1930 (Lippincott, J.B., 1931). A subsequent comprehensive study of the geology and hydrology of the Valley also provided estimates of annual groundwater pumpage and return flows for 1929 through 1944 (USGS, Worts, G.F., 1951). A follow up study provided estimates of the change in groundwater storage during periods prior to 1959 (USGS, Miller, G.A., and Evenson, R.E., 1966).

Several additional studies have been conducted to describe the hydrogeology and groundwater quality of the Valley (USGS, Hughes, J.L., 1977; California CCRWQCB, 1995) and coastal portion of the basin (California DWR, 1970), as well as overall water resources of the Valley (Toups Corp., 1976; SBCWA, 1994 and 1996). Of note are numerous land use surveys (California DWR, 1959, 1968, 1977, 1985, and 1995) and investigations of crop water use (California DWR, 1933, and 1975: Univ. of California Cooperative Extension, 1994; Hanson, B., and Bendixen, W., 2004) that have been used in the estimation of agricultural water requirements in the Valley. Investigation of the Santa Maria groundwater basin provided an assessment of hydrogeologic conditions, water requirements, and water supplies through 1997 and an evaluation of basin safe yield (LSCE, 2000).

1.3. SMVMA Monitoring Program

In accordance with the Stipulation, a monitoring program was initially prepared in 2008 to provide the fundamental data for ongoing annual assessments of groundwater conditions, water requirements, water supplies, and water disposition in the SMVMA (LSCE, 2008). As a basis for designing the monitoring program, historical data on the geology and water resources of the SMVMA were compiled to define aquifer depth zones, specifically a shallow unconfined zone and a deep semi-confined to confined zone, into which a majority of monitored wells were classified based on well depth and completion information. Assessment of the spatial distribution of the wells throughout the SMVMA, as well as their vertical distribution within the aquifer system, provided the basis for designation of two well networks, one each for the shallow and deep aquifer zones. All network wells are to be monitored for groundwater levels, with a subset of those wells to be monitored for groundwater quality. Those wells with inconclusive depth and completion information were originally designated as unclassified wells; in 2009 and 2013, review of groundwater level and quality records allowed classification of some wells into the shallow or deep aquifer zones. Accordingly, the monitoring program was revised in 2009 and 2013 to reflect those minor changes to the well networks.

Commencing in 2019, the US Geological Survey (USGS) ceased groundwater level measurements in a network of approximately 55 wells across the SMVMA, at the direction of the contracting agency, the Santa Barbara County Water Agency (SBCWA). Included in this network are about 30 wells useful for

annual assessment of groundwater conditions in the SMVMA per Stipulation provisions; so those 2019 data were not collected or available for the 2019 assessment. Groundwater level data collected quarterly by the Santa Maria Valley Water Conservation District (SMVWCD, 28 wells in spring, 42 wells in fall) and semi-annually by the TMA under the California Statewide Groundwater Elevation Monitoring Program (CASGEM, an additional 10 wells) were the primary data useful for the 2019 assessment described later in this report.

It is important to note that collaboration between the SMVWCD, the TMA, and LSCE in early 2020 resulted in the designation of a subset of 25 USGS wells for water level measurement. In addition, funds were secured for the semi-annual measurement of the well subset commencing in April 2020, with plans to develop longer term financing for their continued monitoring. When these changes to the SMVMA Monitoring Program (monitoring agency and frequency) are implemented successfully, the program will be revised.

Related to the cessation of USGS water level monitoring in 2019, groundwater quality sampling conducted by the USGS was reduced in 2019, specifically to only about one-half the typical number of wells in the SMVMA monitoring program. As such, a limited amount of groundwater quality data was available from the USGS, augmented by data from water purveyors' wells, for the 2019 assessment described later in this report. Additional work will be needed to restore the groundwater quality monitoring program for annual assessment of groundwater conditions.

Surface water conditions are to be monitored, specifically Twitchell Reservoir releases, stage, and storage, and stream discharge and quality. Climatic conditions, specifically precipitation and reference evapotranspiration data, are to be monitored although, currently, the single California Irrigation Management Information System (CIMIS) climate station in the SMVMA ("Santa Maria II") collects only precipitation data. The TMA is collaborating with DWR to locate and implement another CIMIS station in the SMVMA to provide both precipitation and reference evapotranspiration data. Revision of the SMVMA Monitoring Program will include the additional climate station when implemented.

In addition to the hydrologic data described above, the monitoring program specifies those data to be compiled to describe agricultural and municipal water requirements and water supplies. These include land use surveys, to serve as a basis for the estimation of agricultural irrigation requirements, and municipal groundwater pumping and imported water records, including any transfers between purveyors.

Lastly, the monitoring program for the SMVMA specifies water disposition data be compiled, including treated water discharged at waste water treatment plants (WWTPs) and any water transferred from the SMVMA to the NMMA. As part of this accounting, estimation is to be made of agricultural drainage from the SMVMA and return flows to the aquifer system. For reference, the SMVMA monitoring program is included in **Appendix A**.

In order to complete this annual assessment of groundwater conditions, water requirements, water supplies, and water disposition in the SMVMA, the following data for this year were acquired from the identified sources:

- groundwater level and/or quality data: the SMVWCD, the TMA, the Technical Group for the adjacent NMMA (NMMA-TG), the City of Santa Maria, the Golden State Water Company, and the City of Guadalupe; the USGS; the California Department of Public Health and the Central Coast Regional Water Quality Control Board (CCRWQCB); and the Laguna County Sanitation District (Laguna CSD).
- Twitchell Reservoir stage, storage, and release data: the SMVWCD;
- surface water discharge and/or quality data: the USGS and CCRWQCB;
- precipitation data: the National Weather Service of the National Oceanic and Atmospheric Administration (NOAA), California DWR, and SMVWCD;
- reference evapotranspiration and evaporation data: California DWR (CIMIS) and SMVWCD, respectively;
- agricultural land use data, aerial photography, and satellite imagery: Santa Barbara and San Luis Obispo County Agricultural Commissioner's Offices; United States Department of Agriculture (USDA); and USGS;
- municipal groundwater pumping and imported water data: the City of Santa Maria, the City of Guadalupe, and the Golden State Water Company; and
- treated municipal waste water data: the City of Santa Maria, the City of Guadalupe, the Laguna CSD, and the CCRWQCB.

1.4. Additional Monitoring and Reporting Programs

In 2014, the TMA was designated by the California DWR as the Monitoring Entity for the SMVMA under DWR's CASGEM Program. Compliance with the CASGEM Program requirements, which include at least semi-annual monitoring and reporting of groundwater levels in a subset of shallow and deep wells already within the SMVMA Monitoring Program, is fulfilled by the TMA.

Additionally, in 2016, groundwater resource planning and data reporting requirements under the California DWR Sustainable Groundwater Management Program (SGMA) commenced. Since the SMVMA is part of an adjudicated basin, DWR considers it already managed by the Court and, thus, SGMA groundwater resource planning requirements do not apply. The remaining SGMA requirements for reporting water resources data such as groundwater levels, groundwater pumping, and imported water amounts, are fulfilled by LSCE in its capacity as Management Area Engineer under the Stipulation.

1.5. Report Organization

To comply with items to be reported as delineated in the Stipulation, this annual report is organized into five chapters:

• this Introduction;

- discussion of Hydrogeologic Conditions, including groundwater, Twitchell Reservoir, surface streams, and climate;
- description and quantification of Water Requirements and Water Supplies for the two overall categories of agricultural and municipal land and water use in the SMVMA;
- description and quantification of Water Disposition in the SMVMA; and
- summary Conclusions and Recommendations related to findings regarding water resource conditions in the SMVMA, for this year as well as historically, and recommended actions pertaining to enhanced groundwater recharge, intra-basin water transfer (SMVMA to NMMA), and expansion of the SMVMA monitoring program.

2 HYDROGEOLOGIC CONDITIONS

Current and historical hydrogeologic conditions in the SMVMA, including groundwater conditions, Twitchell Reservoir operations, and stream and climate conditions, are described in the following sections of this Chapter.

2.1. Groundwater Conditions

To provide a framework for discussion of groundwater conditions, the geology of the SMVMA, including geologic structure and the nature and extent of geologic formations comprising the aquifer system, is described in the following section. Current groundwater levels are then described in relation to historical trends in groundwater levels and flow directions in the SMVMA, as well as in context of Stipulation protocol for defining conditions of severe water shortage. Current and historical groundwater quality conditions are also discussed, including general groundwater quality characteristics as well as groundwater quality degradation, specifically due to elevated nitrate concentrations.

2.1.1. Geology and Aquifer System

The SMVMA is underlain by unconsolidated alluvial deposits that comprise the aquifer system, primarily gravel, sand, silt and clay that cumulatively range in thickness from about 200 to 2,800 feet (ft). The alluvial deposits fill a natural trough, which is composed of older folded and consolidated sedimentary and metamorphic rocks with their deepest portions beneath the Orcutt area. The consolidated rocks also flank the Valley and comprise the surrounding hills and mountains; typically, the consolidated rocks do not yield significant amounts of groundwater to wells. The geologic formations comprising the alluvial deposits and the geologic structure within the study area are illustrated in a generalized geologic map (**Figure 2.1-1a**) and two geologic cross sections (**Figures 2.1-1b and 2.1-1c**).

The alluvial deposits are composed of the Careaga Sand and Paso Robles Formation (Fm.) at depth, and the Orcutt Fm., Quaternary Alluvium, and river channel, dune sand, and terrace deposits at the surface (USGS, Worts, G.F., 1951). The Careaga Sand, which ranges in thickness from about 650 ft to a feather edge, is identified as being the lowermost fresh water-bearing formation in the basin (DWR, 1970), resting on the above-mentioned consolidated rocks (specifically, the Tertiary-aged Foxen Mudstone, Sisquoc Fm., and Monterey Shale and the Jurassic/Cretaceous-aged Franciscan Fm., descriptions of which may be found in USGS, Worts, G.F., 1951). Overlying the Careaga Sand is the Paso Robles Fm., which comprises the greatest thickness of the alluvial deposits (from about 2,000 ft to a feather edge); the thickest portion of this formation is located beneath the Orcutt area. Both the Careaga Sand and Paso Robles Fm. underlie the great majority of the SMVMA (see Figures 2.1-1b and 2.1-1c). The Careaga Sand is mainly composed of white to yellowish-brown, loosely consolidated, massive, fossiliferous, medium- to fine-grained sand with some silt and is reported to be predominantly of marine origin (USGS, Worts, G.F., 1951). The Paso Robles Fm. is highly variable in color and texture, generally composed of yellow, blue, brown, grey, or white lenticular beds of: boulders and coarse to fine gravel and clay, medium to fine sand and clay, gravel and sand, silt, and clay (USGS, Worts, G.F., 1951). This formation is reported to be primarily fluvial (stream-laid) in origin and there is no areal correlation

possible between the individual beds, with the exception of a coarse basal gravel of minor thickness in the Santa Maria Valley oil field, generally in the southeast part of the SMVMA.

Above the Paso Robles Fm. and comprising the Orcutt Upland is the Orcutt Fm., which is typically about 160 to 200 ft thick; in the remainder of the SMVMA, the Paso Robles Fm. is overlain by the Quaternary Alluvium, which comprises the majority of the Valley floor and is typically about 100 to 200 ft thick. Further north in the adjacent NMMA, the Paso Robles Fm. is overlain by the Older Dune Sand, which comprises the Nipomo Mesa and ranges in thickness from approximately 400 ft to a feather edge. Along the northeast edge of the Sisquoc plain, the Paso Robles Fm. is overlain by terrace deposits approximately 60 ft thick. The Orcutt Fm. is composed of conformable upper and lower units ("members"), both reported to be mainly of fluvial origin that become finer toward the coast. The upper member generally consists of reddish-brown, loosely compacted, massive, medium-grained clean sand with some lenses of clay, and the lower member is primarily grey to white, loosely compacted, coarse-grained gravel and sand (USGS, Worts, G.F., 1951).

The Quaternary Alluvium is also composed of upper and lower members that are reported to be mainly fluvial in origin. The composition of the upper member becomes progressively finer toward the coast, with boulders, gravel, and sand in the Sisquoc plain area; sand with gravel in the eastern/central Valley area; sand with silt from the City of Santa Maria to a point approximately halfway to Guadalupe; and clay and silt with minor lenses of sand and gravel from that area westward. The lower member is primarily coarse-grained boulders, gravel and sand with minor lenses of clay near the coast. The Older Dune Sand is composed of loosely- to slightly compacted, massive, coarse- to fine-grained, well-rounded, cross-bedded quartz sand that is locally stained dark reddish-brown (California DWR, 1999). The terrace deposits, in general, are similar in composition to the coarse-grained parts of the Quaternary Alluvium.

The alluvial deposits comprising the aquifer system lack peat (organic) layers and include thin, discontinuous clay lenses, without thick sections of clay at greater depths. Thus, the potential is remote for deep land subsidence to occur as the deposits dewater during periods of declining groundwater levels. There are no known reports of, nor the potential for, land subsidence in the SMVMA, as noted in a recent technical report on the occurrence of subsidence through California (California DWR, 2014).

Two geologic cross sections illustrate several points about the geologic structure and variable aquifer thickness throughout the SMVMA. Longitudinal geologic cross section A-A' (see **Figure 2.1-1b**) begins in the area near the mouth of the Santa Maria River, traverses the Orcutt Upland, and terminates in the Sisquoc plain area near Round Corral, immediately southeast of the SMVMA. It shows the relative thicknesses of the various geologic formations and their general "thinning" from the central valley area toward the Sisquoc plain. This cross section also shows the Quaternary Alluvium and Orcutt Fm., essentially adjacent to each other and comprising the uppermost aquifer in the SMVMA, divided into the above-described upper and lower members.

Transverse geologic cross section B-B' (see **Figure 2.1-1c**) begins in the Casmalia Hills, traverses the western portion of the Valley (near the City of Guadalupe) and the southern Nipomo Mesa, and terminates at Black Lake Canyon. It shows the prominent asymmetrical syncline (folding of the consolidated rocks and Paso Robles Fm.) within the SMVMA and adjacent NMMA, with the deepest portion of Paso Robles Fm. toward the southern edge of the SMVMA, gradually becoming thinner and more shallow toward the north where it extends beneath the NMMA. This cross section also shows that both the upper and lower members of the Quaternary Alluvium extend north to the Santa Maria River, but only the upper member extends beyond the River to the southern edge of the Nipomo Mesa, and neither member extends northward beneath the Mesa.

Several faults have been reported to be located in the SMVMA and adjacent portion of the NMMA. The Santa Maria and Bradley Canyon faults, located in the Valley in the area between the City of Santa Maria and Fugler Point (at the confluence of the Cuyama and Sisquoc Rivers to form the Santa Maria River), are concealed and they are reported to be northwest-trending, high-angle faults, that vertically offset the consolidated rocks, Careaga Sand, and Paso Robles Fm., but not the overlying Quaternary Alluvium or Orcutt Fm. (USGS, Worts, G.F., 1951). The Oceano and Santa Maria River faults are of a similar nature (the latter fault also has a significant strike-slip component of movement), but they are primarily located in the southern Nipomo Mesa. The maximum vertical offset on the Oceano fault is reported to be in the range of 300 to 400 ft within the Careaga Sand and Paso Robles Fm.; on the other faults, the vertical offset is reported to be much less, within the range of 80 to 150 ft (USGS, Worts, G.F., 1951; California DWR, 1999). However, these faults do not appear to affect groundwater flow within the SMVMA, based on the review of historical groundwater level contour maps (USGS, Worts, G.F., 1951; LSCE, 2000).

There is no known structural (e.g., faulting) or lithologic isolation of the alluvial deposits from the Pacific Ocean, i.e., the Quaternary Alluvium, Orcutt Fm., Careaga Sand, and Paso Robles Fm. aquifers continue beneath the Ocean. Thus, there is geologic continuity that permits groundwater discharge from the SMVMA to the Ocean, and the potential exists for salt water to intrude into the coastal (landward) portions of the aquifers if hydrologic conditions within them were to change.

The aquifer system in the SMVMA is comprised of the Carega Sand, Paso Robles Fm., the Orcutt Fm., and the Quaternary Alluvium (USGS, Worts, G.F., 1951). The upper member of the Quaternary Alluvium is consistently finer-grained than the lower member throughout the Valley. Further, the upper member becomes finer grained toward the Ocean such that it confines groundwater in the lower member from the approximate area of the City of Santa Maria's waste water treatment plant westward (approximately eight miles inland from the coast). The result of this has been some artesian conditions in the western valley area (historically, flowing artesian wells were reported until the early 1940s in the westernmost portion of the Valley) (USGS, Worts, G.F., 1951). More recently, many water supply wells belonging to local farmers in the western valley area, specifically in the Oso Flaco area, and monitoring wells located at the coast began flowing again in response to rising confined groundwater levels, such as during the winter of 1999.

Analysis of the geology, groundwater levels, and groundwater quality indicates that the aquifer system varies across the area and with depth, and this variation was the basis for the shallow and deep aquifer zone designations of the SMVMA monitoring program (LSCE, 2008). In the central and major portion of the SMVMA, there is a shallow unconfined zone comprised of the Quaternary Alluvium, Orcutt Fm., and uppermost Paso Robles Fm., and a deep semi-confined to confined zone comprised of the remaining Paso Robles Fm. and Careaga Sand. In the eastern portion of the SMVMA where these formations are much thinner and comprised of coarser materials, particularly in the Sisquoc Valley, the aquifer system is essentially uniform without distinct aquifer depth zones. In the coastal area where the surficial deposits (upper members of Quaternary Alluvium and Orcutt Fm.) are extremely fine-grained, the underlying formations (lower members of Quaternary Alluvium and Orcutt Fm., Paso Robles Fm., and Careaga Sand) comprise a deep confined aquifer zone.

2.1.2. <u>Groundwater Levels</u>

Groundwater levels within the SMVMA have fluctuated greatly since the 1920's, when historical water level measurements began, with marked seasonal and long-term trends, as shown by a collection of representative groundwater level hydrographs from various areas throughout the SMVMA (**Figure 2.1-2**). The areas are designated on **Figure 2.1-2** for illustrative purposes only, and include the so-called Coastal, Oso Flaco, Central Agricultural, Municipal Wellfield, Twitchell Recharge, and Sisquoc Valley areas. The historical groundwater level hydrographs illustrate that widespread decline in groundwater levels, from historical high to historical low levels, occurred between 1945 and the late 1960's. The declines ranged from approximately 20 to 40 ft near the coast, to 70 ft near Orcutt, to as much as 100 feet further inland (in the area just east of downtown Santa Maria). Those declines were observed in both the shallow and deep aquifer zones and are interpreted today to have been the combined result of progressively increasing agricultural (and to a lesser degree, municipal) demand and long-term drier than normal climatic conditions during that period.

Since the late 1960's, the basin has experienced a general long-term stability as groundwater levels in both aquifer zones have fluctuated between historical-low and near historical-high levels over alternating five- to 15-year periods. Groundwater levels throughout the SMVMA have shown this trend, but with different ranges of fluctuation (see Figure 2.1-2); and groundwater levels have repeatedly recovered to near or above previous historical-high levels, most recently in 2002. Shallow groundwater levels in the Sisquoc Valley fluctuated somewhat differently in that they did not fully recover to historical high levels by 2002. In the primary areas of recharge along the Santa Maria River, groundwater level fluctuations are greater in the shallow aquifer zone than the deep (see Twitchell Recharge Area and Central Agricultural Area hydrographs). Conversely, in the Municipal Wellfield and Coastal Areas, groundwater level fluctuations are greater in the deep aquifer zone. Hydrographs from wells along the coastal portion of the SMVMA show that groundwater elevations have remained above sea level, with deep (confined) groundwater levels rising enough to result in flow at the ground surface, throughout the historical period of record. The periodic groundwater level fluctuation since the late 1960's (with a long-term stability) have apparently been due to intermittent wet and dry climatic conditions, with natural recharge during wet periods complemented by supplemental recharge along the Santa Maria River from the Twitchell Reservoir project (since becoming fully operational in the late

1960's). Long-term stability in groundwater levels may be partially attributed to a general "leveling-off" of agricultural land and water use in the basin since the early to mid-1970's, as further described in Chapter 3.

Most recently, since 2002, groundwater levels in both the shallow and deep zones of the SMVMA were in a gradually declining trend that became more rapid in 2012. By the Fall of 2017, shallow groundwater levels in the Twitchell Recharge and Sisquoc Valley areas recovered substantially with slight additional recovery in 2018 and 2019. In the remaining SMVMA, shallow and deep groundwater levels observed in 2016 through 2019 were essentially the same, remaining slightly above historical low levels (see **Figure 2.1-2**).

Particularly in light of prevailing land use and water requirements, the overall groundwater level decline beginning in 2002 is considered to be primarily due to the fact that Twitchell Reservoir releases, for instream supplemental groundwater recharge, and Sisquoc River discharge, have been well below the historical average in most years since 2000. More specifically, there were no Twitchell Reservoir releases in 10 of the last 18 years, including in 2013 through 2016, until they resumed in the Fall of 2017 through Spring 2018, then during all months of 2019. Further, the Sisquoc River discharge was well below average in almost all years since 2002, including in 2018. The recent declining trend in shallow groundwater levels was slowed or reversed during years 2005-2006, 2010-2011, late 2017, and 2019. During these years, releases from Twitchell Reservoir, as well as discharge in the Sisquoc River, were near or above average following above-average rainfall periods.

As in 2015 through 2018, groundwater levels measured during 2019 in one deep well in the Twitchell Recharge Area, specifically well 10N/33W-30G1, were below the historical low water level observed in this well in 1991 (although those groundwater levels rose in 2019) (see **Figure 2.1-2**). However, water levels in numerous shallow and deep wells in this same area with long historical records (covering previous drought periods) remained above their respective historical low. Further, it is likely that recharge derived from the Fall 2017, Winter/Spring 2018, and 2019 Sisquoc River and Twitchell Reservoir flows has contributed to raising shallow groundwater levels in the same area (see **Figure 2.1-2**, well 10N/33W-19B1). Thus, it appears the 2019 water levels in well 30G1 remain a localized lowering of water levels.

As noted above, shallow and deep groundwater levels across the great majority of the SMVMA remained slightly above historical low levels in 2019. This includes along the coast where groundwater levels are well above sea level, indicating that the conditions conducive to sea water intrusion are absent. As such, the groundwater level conditions observed in 2019 in the SMVMA do not meet Stipulation provisions defining a condition of severe water shortage, as will be discussed in Section 5.1.

Groundwater beneath the SMVMA has historically flowed to the west-northwest from the Sisquoc area toward the Ocean, and this remained the case during 2019 as illustrated by contour maps of equal groundwater elevation for the shallow and deep aquifer zones (**Figures 2.1-3a through 2.1-3d**). A notable feature in the contour maps is the limited areal coverage and density of wells with water level data due to the previously mentioned cessation of well measurements by the USGS in 2019. As in most

years of study in the basin, a notable feature in the 2019 contour maps is the widening of groundwater level contours beneath the central-south and western portions of the SMVMA that indicates a reduced (flatter) groundwater gradient in this area. This likely reflects the fact that the majority of aquifer system recharge derives from streamflow in the Sisquoc and Santa Maria Rivers, specifically in the eastern portion of the SMVMA upstream of Bonita School Crossing Road, and to a minor extent from streamflow in creeks draining the Casmalia and Solomon Hills along the southern portion of the SMVMA. This is supported by the presence of a reduced groundwater gradient in this area since at least 1960 (USGS, Miller, G.A., and Evenson, R.E., 1966; USGS, Hughes, J.L., 1977; LSCE, 2000).

The reduced gradient likely also reflects ongoing groundwater pumping in and around the municipal wellfield near the Santa Maria Airport and Town of Orcutt where numerous deep municipal water supply wells of the City of Santa Maria and the Golden State Water Company (GSWC), and nearby agricultural wells, operate. This is supported by the observance that, in this area, the groundwater gradient in the deep aquifer zone is more reduced (flatter) than in the shallow zone. Further, groundwater elevations in the deep zone are markedly lower than those in the shallow zone in this area, with smaller differences in groundwater elevations between depth zones in other portions of the SMVMA. Importantly, while the reduced groundwater gradient near the municipal well field has had the effect of slowing the movement of groundwater through that portion of the SMVMA, it has not stopped or reversed the direction of groundwater flow.

Also notable from the contour maps is the overall seasonal difference in groundwater levels across the SMVMA between the spring and fall periods. The timing and magnitude of the groundwater level changes in 2019 reflect the spring recharge from the Sisquoc and Santa Maria Rivers (contributing to a rise in groundwater levels near the rivers) and the area-wide groundwater pumping for seasonal agricultural irrigation (contributing to a decline in levels elsewhere). Groundwater pumping for municipal supply increased slightly during summer to fall and could have contributed to groundwater level lowering in/near the Municipal Wellfield area. Importantly, during 2019, a seaward gradient for offshore groundwater flow was maintained, and coastal groundwater elevations remained well above sea level (typically near 15 ft, NAVD88), in both the shallow and deep aquifer zones. Across the coastal boundary of the SMVMA, the offshore flow of groundwater in the shallow aquifer zone appears to have been reduced by early spring (see **Figure 2.1-3c**). Regarding groundwater flow from the SMVMA toward the southern coastal Nipomo Mesa, it appears to either meet groundwater pumping demands in the area or eventually flow offshore along the coastal boundary of the NMMA.

Additional information about the seasonal fluctuation of groundwater levels in and near the SMVMA, in particular along its northern boundary with the NMMA near Oso Flaco Valley, is derived from hourly or daily groundwater level measurements made since late 2013 by transducers in two monitoring wells belonging to the San Luis Obispo County Department of Public Works (SLODPW) in that area. A groundwater level hydrograph for one well located in the northwestern edge of Santa Maria Valley (**Figure 2.1-4a**) illustrates how, in 2014 through 2016 and in 2019, the spring high level occurs in January or February. Further, a seasonal decline in water levels is observed between the spring high and fall low

(September or October) each of these years, on the order of 10 to 16 ft. Groundwater elevations in 2019 were very similar to those in 2016, but there is an overall decline in groundwater levels such that year-end levels are one to five feet lower than at the beginning of the year.

A groundwater level hydrograph for the second well, located in the southern central edge of the Nipomo Mesa (**Figure 2.1-4b**) indicates very similar groundwater level fluctuations as observed in the Oso Flaco Valley. Spring high levels occur in January or February but are followed by a larger seasonal decline to the lowest levels in September or October, on the order of 25 ft. Groundwater elevations in 2019 were very similar to those in 2016, with an overall decline in groundwater levels, and year-end levels are one to four feet lower than those observed at the beginning of the year.

Thus, the frequent groundwater level data from the transducers has provided detailed information about the timing of spring high and fall low water levels in the SMVMA. While it is locally understood that spring high levels in the SMVMA typically occur in late February to early March, the transducer data indicate that the spring high levels have been occurring earlier in January or earlier February.

The transducer data also indicate that the period of spring high groundwater levels in the SMVMA, following the partial recovery of groundwater levels over each winter, is typically brief. It is presumed that seasonal agricultural irrigation has been commencing as early as January, perhaps due to ongoing drought and/or changing irrigation practices, which could contribute to early declines in groundwater levels. Aquifer recharge from Sisquoc and Santa Maria River discharge also likely contributes to the timing and magnitude of groundwater level changes in this area of the SMVMA each year.

Given that a common objective of groundwater monitoring programs is to measure the spring high and fall low groundwater levels, the USGS has, until 2019, come the closest of all measuring agencies to meeting this objective (with early to mid-March and mid-October measurements). The transducer data provide the magnitude of groundwater level decline that can occur in this portion of the SMVMA between mid-March and mid-April, from five to eight feet. This in turn illustrates the magnitude of inconsistency in spring groundwater level data collected in the SMVMA by the USGS (previously, early to mid-March), the SMVWCD (early April), and the SLOPWD (mid- to late April). Alternatively, the transducer data indicate that groundwater levels decline to (and maintain) their fall low period during mid-September to mid-October, thus confirming the proper timing of fall measurements made in the SMVMA and adjacent NMMA by all these measuring agencies.

If future spring groundwater level monitoring were conducted by the SMVWCD and TMA earlier in the year (e.g., February), spring high conditions in most of the SMVMA would be better understood. The SLOPWD have indicated in the past that their data collection (from wells near Oso Flaco Valley) needs to continue in mid- to late April, due to considerations involving well owners and weather conditions. Spring data sets from February and April would be incompatible for assessment of groundwater conditions. Alternatively, future spring monitoring in the SMVMA could be conducted in April to have a consistent measuring period among the SMVWCD, TMA, and SLOPWD, although missing the spring high conditions.

2.1.3. Groundwater Quality

Groundwater quality conditions in the SMVMA have fluctuated greatly since the 1930's, when historical water quality sampling began, with marked short- and long-term trends. Groundwater quality in the SMVMA historically reflects the various natural sources of recharge to the aquifer system, most notably streamflows of the Cuyama and Sisquoc Rivers that provide recharge along the Santa Maria River. The great majority of groundwater in the SMVMA, primarily in the eastern and central portions of the Santa Maria Valley and in the Sisquoc Valley, had historically been of a calcium magnesium sulfate type originating from the Cuyama and Sisquoc River streamflows. Further, groundwater was historically of better quality toward the Orcutt Upland, Nipomo Mesa, the City of Guadalupe, and coastal areas (Lippincott, J.B., 1931).

With development of the Valley and surrounding areas in the 1940's through 1970's, including expansion of the agricultural and urban areas and addition of the Twitchell Reservoir project, groundwater quality conditions changed within the SMVMA. The changes included improvement of the general groundwater quality in the eastern to central part of the Santa Maria Valley in and near the area of Twitchell Reservoir recharge, including the current-day municipal wellfield near the Town of Orcutt. Additionally, degradation of groundwater quality occurred further west and downgradient in the Valley, specifically with elevated general mineral and nitrate concentrations (USGS, Hughes, J.L., 1977).

Subsequently, from the 1970's through current day, general mineral concentrations in groundwater have remained essentially unchanged, including the occurrence of better-quality water in the SMVMA's eastern, central, and southern portions and poorer quality water to the west. Further, groundwater quality is generally slightly better and with less fluctuation in the deep aquifer zone compared to the shallow, as shown by a map with representative historical groundwater quality graphs from areas throughout the SMVMA (**Figure 2.1-5**). A notable feature of the map is the limited areal coverage and density of wells with water quality data due to the previously mentioned reduction of well sampling by the USGS in 2019. Discussion of the groundwater quality in 2019 and over the historical period of record follows by constituent, specifically total dissolved solids (TDS) and nitrate (as NO₃), and by aquifer zone. Assessment of historical TDS and nitrate concentrations provides a broad understanding of groundwater quality conditions in the SMVMA, including aquifer system characteristics such as the sources of recharge and the nature of groundwater flow.

TDS values in much of the SMVMA have generally remained stable at or below the California Department of Public Health's secondary standard (e.g., for taste and odor) of 1,000 milligrams per liter (mg/L). This standard is exceeded only in localized portions of the aquifer, primarily in the Coastal Area.

TDS, shallow zone, 2019: TDS concentrations were generally 600 to 1,000 mg/L in the Twitchell Recharge and Central Agricultural Areas, 700 to 800 mg/L in the Municipal Wellfield Area, and 1,000 mg/L in the Coastal Area. TDS concentrations in the Sisquoc Valley have been about 600 mg/L, but no data are available from 2016 through 2019.

TDS, deep zone, 2019: TDS values in the deep zone of the Twitchell Recharge and Municipal Wellfield areas are typically lower than in the shallow zone. However, in 2019, a single deep well was analyzed in these areas, with a reported concentration of 800 mg/L (well 10N/34W-12A_S. This was due to the limited groundwater quality sampling conducted by the USGS (Valley wide), as well as 2019 being an "off year" in the three-year cycle of municipal well testing (GSWC Orcutt system) for TDS. TDS values in the deep zone were higher than in the shallow zone in the north Coastal Area (wells 11N/36W-35J), between 700 and 1,500 mg/L. TDS values from a single deep well in the Central Agricultural Area were about 800 mg/L in 2019 (well 10N/35W-09E5); no TDS data are available for the Sisquoc Valley Area since 2016.

Nitrate concentrations in much of the SMVMA, in contrast to TDS, remain elevated, in fact above the primary drinking water standard (health based) of 45 mg/L nitrate-NO₃. Exceedance of the nitrate standard occurs more in the shallow than deep zone.

Nitrate, shallow zone, 2019: Nitrate concentrations generally ranged from less than 0.2 mg/L to 52 mg/L in the Twitchell Recharge Area, 44 to 58 mg/L in the Municipal Wellfield Area, 16 to 52 mg/L in the Central Agricultural Area, and less than 0.2 mg/L in the Coastal Area. No data were available for the Sisquoc Valley Area in 2016 through 2019.

Nitrate, deep zone, 2019: Nitrate concentrations in most of the SMVMA remained markedly lower than in the shallow zone, generally less than 0.4 mg/L in the Twitchell Recharge Area and from 5 to 32 mg/L in the Municipal Wellfield Area. Nitrate concentrations were 2 to 3 mg/L in the south Coastal Area and 2 to 100 mg/L in the north Coastal Area. Nitrate concentrations from a single deep well in the Central Agricultural Area were between 17 and 23 mg/L in 2019 (well 10N/35W-09E5); no nitrate data are available for the Sisquoc Valley Area since 2016.

Focus is provided herein on **historical** groundwater quality conditions along the **coast** where ongoing assessment of potential conditions of sea water intrusion is of particular importance. During an investigation conducted in the late 1960's, for which two coastal monitoring well sets were constructed, localized areas of degraded shallow groundwater were identified but concluded at the time to be due to environmental factors other than sea water intrusion (California DWR, 1970). Review of the coastal monitoring well data record commencing in the mid-1970s, specifically TDS values, provides an indication of whether sea water intrusion has occurred in the coastal SMVMA. Review of coastal nitrate concentrations provides a measure of the extent and magnitude of water quality degradation from land use activities further inland. Historical water quality graphs for these wells are provided in Appendix B.

Coastal TDS, shallow zone, historical: TDS concentrations gradually increased between 1980 and 1990, from 750 to 900 mg/L, before stabilizing in a range between 900 and 1,400 mg/L.

Coastal TDS, deep zone, historical: TDS concentrations in the deepest portions of the coastal aquifer have remained stable between 750 and 800 mg/L. In fact, TDS values in all deep wells of the southern well set (10N/36W-02Q) have been stable, typically less than 700 mg/L. However, an increasing trend

since 1985 is observed in deep wells (200 to 500 ft deep) of the northern well set (11N/36W-35J), from approximately 1,000 to 1,350 mg/L, with some wells reaching 1,500 mg/L.

Coastal Nitrate, shallow zone, historical: Nitrate concentrations have been non-detect (<0.18 or 0.2 mg/L) since monitoring commenced.

Coastal Nitrate, deep zone, historical: Nitrate concentrations in the deepest portions of the coastal aquifer have been at or near non-detect since monitoring began. In fact, this is the case in all deep wells of the southern well set (10N/36W-02Q). However, an increasing trend since 1985 is observed in deep wells (200 to 500 ft deep) of the northern well set (11N/36W-35J), from approximately 10 to 50mg/L, with one well reaching 100 mg/L.

This discussion of groundwater quality conditions covers the most important and most common inorganic constituents in groundwater in the SMVMA: salts and nutrients. The large majority of recharge to the aquifer system in the SMVMA derives from streams that have naturally occurring but elevated concentrations of salt. The largest contribution of man-made chemical constituents to the aquifer system in the SMVMA derives from fertilizer applications, specifically nitrogen (nitrate), to agricultural lands.

In assessing groundwater quality conditions of the SMVMA, TDS analysis is the most useful measure of salt content in the groundwater in that it sums all dissolved salts, the combined anion and cation components of which are generally conservative in their migration through the aquifer system. As a result, the analysis of TDS in the groundwater is very useful in identifying the areas and mechanisms of aquifer recharge to the SMVMA, from both natural and man-made sources. Analysis of nitrogen is a requirement of public water purveyors due to the known impacts to human health from consuming nitrogen. As a result, the analysis of nitrogen in the groundwater is protective of human health and useful in identifying the sources of nitrogen contamination in the SMVMA.

2.2. Twitchell Reservoir Operations

In order to describe Twitchell Reservoir operations, monthly records of reservoir stage, storage, and releases were compiled, and recorded observations of reservoir conditions were noted. The historical stage, storage, and releases through 2019 are described in relation to observed climatic conditions in the SMVMA.

2.2.1. <u>Reservoir Stage and Storage</u>

Historical stage and storage in Twitchell Reservoir, for which reliable records begin in 1967, indicate a typical seasonal rise with winter and spring rain, followed by decline through subsequent spring and summer releases. Reservoir stage has risen to as high as about 640 ft mean sea level (msl), corresponding to storage of nearly 190,000 acre-feet (AF), on several occasions during the winter and spring months of years during which rainfall amounts were substantially higher than average. Historical rises in stage have been rapid, occasionally over one or two months, with subsequent declines gradually spread over the subsequent year or multiple years. During those years when releases have essentially

emptied the reservoir for purposeful supplemental groundwater recharge through the Santa Maria River channel, the dam operator recorded the associated minimum reservoir stage, which has risen over time from about 480 ft msl in 1968, to 525 ft msl since 1986. This rise reflects the long-term filling of former dead pool storage (about 40,000 AF below the reservoir outlet for release from conservation storage) with sediment that has naturally occurred with operation of the project (SMVWCD, 1968-2019). This filling has been accelerated by sediment-laden surface and stream runoff deriving from watershed areas that have recently experienced large fires. These seasonal fluctuations and long-term rise in minimum stage, shown in relation to the reservoir conservation, flood control, and surcharge pools, are illustrated in a graph of historical reservoir stage and storage (**Figure 2.2.1a**).

It is noteworthy that the sedimentation of the former dead pool storage below the conservation outlet in Twitchell Reservoir has not impeded the conservation of runoff for subsequent release for downstream groundwater recharge. Except for a few individual years over the life of the reservoir, accumulated storage in any year has been less than the designated active conservation pool of 109,000 AF. In the infrequent wet years when greater storage could be conserved, e.g. 1969, 1978, 1983, 1995, and 1998, the SMVWCD has been permitted to temporarily utilize some of the dedicated flood control pool (89,000 AF) to conserve those additional inflows and then release them soon thereafter for downstream recharge. Total storage has never exceeded the combined conservation pool and flood control pool storage volume (198,000 AF) and has never invaded the uppermost surcharge pool (159,000 AF above the conservation and flood control pools) in the overall reservoir. Of note is that a sediment removal project is currently being implemented at Twitchell reservoir as part of the SMVWCD ongoing operations and maintenance work.

Reservoir storage has historically risen to between 150,000 and nearly 190,000 AF during the winter and spring months of years during which rainfall was substantially higher than average, with storage commonly below 50,000 AF during most other years. As can be seen on **Figure 2.2-1a**, reservoir storage has repeatedly dropped to essentially zero during periods of below-average rainfall, including those associated with drought conditions in 1976-77, 1987-90, and 2012-16 and 2018. In fact, reservoir storage has been essentially zero during most the overall drier climatic period that began in 2002. In 2019, water in storage accumulated to the maximum of 50,700 AF in April before declining to almost zero in December.

Briefly during the drier climatic period since 2002, such as in both 2005 and 2006 when rainfall was above average, about 50,000 AF of storage were accrued, all of which was released for downstream groundwater recharge. In late 2010 into early 2011, again in response to above-average rainfall, storage accrued by April 2011 to almost 93,000 AF (and the stage to 615 ft msl) with releases commencing in February 2011 and continuing through March 2012. From then until 2017, only minor amounts of water were conserved that subsequently evaporated and/or were lost to seepage such that no releases were possible. Importantly, with above-average rainfall occurring in early 2017 and 2019, reservoir storage increased to 74,800 and 50,700 AF, respectively, before all water in storage was depleted by project releases.

2.2.2. <u>Reservoir Releases</u>

Twitchell Reservoir annual releases for in-stream groundwater recharge since 1967 have ranged from zero during low rainfall years and drought periods to a maximum of 243,660 af in 1998, as illustrated in a bar chart of annual reservoir releases (Figure 2.2-1b). In general, and most notably in the Twitchell Recharge Area, groundwater levels have tended to track Twitchell releases since the beginning of reservoir operations (see Figure 2.1-2 and 2.2-1b). The long-term average annual release amount (for the period 1967 through present) is 47,100 acre-feet per year (AFY), with below-average releases during roughly two-thirds of those years. The five-year period from 1995 through 1999 is notable for continual releases in amounts well above the annual average, reflecting a wetter climatic period from 1993 through 1998. Also notable are multiple year periods when releases dropped to zero, specifically from 1987 through 1990 and from 2002 through 2004, reflecting the drier climatic conditions during those periods of time. While releases in 2005 and 2006 amounted to about 106,000 and 80,000 AF, respectively, drier climatic conditions persisted with no releases for in-stream groundwater recharge in 2009 or 2010. The release of nearly 99,100 AF of water from Twitchell Reservoir was conducted from February 2011 through March 2012, with the latter marking the beginning of a severe drought with no releases through 2016. In 2017, releases began in August and continued through the remainder of 2017 and into April 2018. Total releases were estimated as 52,640 AF in 2017 and 12,140 AF in 2018 (based on recorded reservoir storage and climatic data for 2017-18). In 2019, releases were recorded and occurred every month, totaling 46,190 AF.

Importantly, the magnitude of the effect on reservoir releases of the most recent dry climatic period commencing in 2002 can be seen in a comparison of the calculated average reservoir releases for the following selected periods of time:

Period of record 1967 – 2019 (47,100 AFY); Pre-dry period 1967 – 2001 (59,300 AFY); and Most recent dry period 2002 – 2019 (23,400 AFY).

The average amount of water released during the most recent dry period (2002 - 2019) is less than onehalf the average for the overall period of record (1967 - 2019) and essentially only one-third the average for the pre-dry period (1967 - 2001).

2.3. Streams

The surface water hydrology of the SMVMA is characterized in this section, specifically the current conditions in relation to historical trends in stream discharge and quality.

2.3.1. Discharge

The main streams entering the SMVMA are the Cuyama and Sisquoc Rivers; these rivers join on the Santa Maria Valley floor near Garey and become the Santa Maria River, which drains the Valley from that point westward (see **Figure 1.1-1 and Appendix A, Figure 3**). The headwaters of the Sisquoc River include a portion of the San Rafael Mountains and Solomon Hills, and the River's main tributaries within

the SMVMA are Foxen, La Brea, and Tepusquet Creeks. Streamflow in the Sisquoc River and its tributary creeks have remained uncontrolled through the present. The Cuyama River drains a portion of the Sierra Madre Mountains, including the Cuyama Valley, and streamflow into the Santa Maria River has been controlled since construction of Twitchell Dam between 1957 and 1959. The Santa Maria River receives minor streamflows from two small tributaries, Suey and Nipomo Creeks, along its course toward the City of Guadalupe and the Pacific Ocean. In the southern SMVMA, Orcutt Creek drains a part of the Solomon Hills (Solomon Canyon) and the Orcutt area, at which point a portion of the Creek discharge is diverted by pipeline to the A Street retention basin north of the Santa Maria Airport (Santa Barbara County Flood Control & Water Conservation District, SBCFC&WCD, 1985; personal communication, T. Gibbons, SMVWCD, January 25, 2017). Orcutt Creek continues to flow westward, receiving intermittent flow from small drainages from the south, before being joined by Green Canyon Channel near Guadalupe, to flow toward the mouth of the Santa Maria River.

Stream discharge in the Cuyama River below the dam, recorded during the initial period of Twitchell project operations between 1959 and 1983, averaged 37,350 AFY. As discussed above, Twitchell Reservoir releases have averaged 47,100 AFY from 1967 through 2019. The historical variation in reservoir releases and Cuyama River streamflow is shown in a bar chart of annual surface water discharge for the River (**Figure 2.3-1a**). Cuyama River stream discharge, which comprises the largest source of SMVMA groundwater recharge, has ranged over the historical period of record from no streamflow during several drought years, including as recently as 2010 and 2013 through 2016, to a high of almost 250,000 AF during 1998. Releases in 2019 were slightly below average at about 46,190 AF.

Stream discharge in the Sisquoc River, recorded at gauges at the southeast end of the Sisquoc plain ("near Sisquoc") and further downstream at the opening to the SMVMA ("near Garey"), average 33,850 (absent data from years 1999-2007) and 35,920 AFY, respectively, over the historical period of record.¹ The Sisquoc River total discharge was well above average in 2019, 52,530 AF ("near Sisquoc") and 55,550 AF ("near Garey").

The Sisquoc River downstream gauge ("near Garey") provides a measure of the stream discharge entering the SMVMA from the Sisquoc plain. The gauge reflects inflow from the headwaters of the Sisquoc River and its tributaries, as well as gains from and losses to the shallow aquifer in the Sisquoc plain. The historical variation in Sisquoc River streamflow is shown in a bar chart of annual surface water discharge for the River at both gauges (**Figure 2.3-1b**). Sisquoc River stream discharge to the SMVMA ("near Garey" gauge), which comprises a large source of SMVMA groundwater recharge, has ranged over the historical period of record from no streamflow during several drought years to over 300,000 AF during 1998; again, the 2019 annual discharge (provisional/approved) into the SMVMA was well above average at 55,550 AF.

Of note is that the upstream Sisquoc River gauge ("near Sisquoc") was non-operational, and thus no data are available, from 1999 through 2007. Further, discharge amounts in the tributaries Foxen, La Brea, and Tepusquet Creeks have not been recorded since the early 1970's (early 1980's for the latter

¹ These values of mean annual discharge include provisional (October-December 2019) discharge data.

creek), when gauge operations were discontinued. As a result, the net amount of groundwater recharge in the Sisquoc plain from the Sisquoc River currently cannot be quantified. Reestablishment and monitoring of these currently inactive gauges (Foxen, La Brea, and Tepusquet Creeks) in some manner would provide for better understanding of the magnitude and distribution of recharge from the Sisquoc River in the Sisquoc Valley.

Streamflow in the Santa Maria River has been recorded at two gauges during varying periods of time ("at Suey Crossing" and "at Guadalupe," see **Appendix A, Figure 3**). At the Suey Crossing gauge, 2019 annual discharge was 33,640 AF, substantially greater than the 4,100 AF of discharge recorded for 2018. Comparison of this amount to the combined Sisquoc River discharge and Twitchell releases indicates that substantial recharge occurs along the portion of the Santa Maria River upstream from Suey Crossing. The available historical Santa Maria River (at Suey Crossing) streamflow data are shown in a bar chart of annual surface water discharge for the River (**Figure 2.3-1c**).

At the Guadalupe gauge, which was operational between 1941 and 1987, stream discharge ranged from no streamflow during numerous years to almost 185,000 AF during 1941, and averaged 26,800 AFY prior to the commencement of Twitchell project operations compared to 17,600 AFY during the period of Twitchell project operations. The historical variation in Santa Maria River (at Guadalupe) streamflow is shown in a bar chart of annual surface water discharge for the River (**Figure 2.3-1d**). The reduction in streamflow at Guadalupe is attributed to Twitchell project operations, which are intended to maximize recharge along the more permeable portion of the River streambed by managing reservoir releases to maintain a "wetline" (downstream extent of streamflow) only as far as the Bonita School Road Crossing.

Supplemental recharge to the Santa Maria Valley from Twitchell project operations has been estimated to be about 32,000 AFY based on comparison of pre- and post-project net losses in streamflow between Garey and Guadalupe (LSCE, 2000). The estimation does not account for changes in climatic conditions between the pre-project (overall dry) and post-project (overall wet) periods or losses/gains along the Santa Maria River due to other processes, which could result in changes in the amount of water available for recharge over time. As a result of discontinued stream discharge measurements at Guadalupe since 1987, combined with the lack of gauged data for Suey and Nipomo Creeks, the net amount of groundwater recharge in the Santa Maria Valley from the Santa Maria River currently cannot be updated. Reestablishment and monitoring of these currently inactive gauges (Suey Creek, Nipomo Creek, and Santa Maria River at Guadalupe) in some manner would provide for better understanding of the magnitude and distribution of streamflow and recharge from the Santa Maria River.

Stream discharge in Orcutt Creek, recorded at Black Road Crossing from 1983 through the present (absent data from years 1992 through 1994), averages about 1,530 AFY, ranging from essentially no streamflow during several years to just over 10,000 AF in 1995; in 2019, stream discharge was above average, about 1,840 AF. The historical variation in streamflow is shown in a bar chart of annual surface water discharge for the creek (**Figure 2.3-1e**). While it can be expected that much of the streamflow recorded at the Black Road gauge ultimately provides groundwater recharge to the SMVMA, it is not known how much Creek discharge is diverted upstream of the gauge to the A Street retention basin.

Further, it is not known how much groundwater recharge or discharge occurs along the length of Orcutt Creek, particularly upstream from the gauge to the point where Orcutt Creek enters the SMVMA.

2.3.2. Surface Water Quality

The majority of recharge to the SMVMA has historically derived from streamflow in the Santa Maria River originating from the Cuyama and Sisquoc Rivers. Thus, groundwater quality in much of the SMVMA has historically reflected the water quality of streamflow in the Cuyama and Sisquoc Rivers. Water quality in the rivers depends on the proportion and quality of the rainfall runoff and groundwater inflow contributing to streamflow in their respective watersheds above the Santa Maria Valley. The Cuyama River watershed includes the Cuyama Valley, which is reported to be underlain by geologic formations containing large amounts of gypsum; the Sisquoc River watershed is primarily steep terrain underlain by consolidated rocks (USGS, Worts, G.F., 1951).

The quality of the streamflow in both the Cuyama and Sisquoc Rivers has historically been of a calcium magnesium sulfate type, although the Sisquoc River contains less sulfate and more bicarbonate than the Cuyama River. The Cuyama River quality has improved at two points in time during the historical period, specifically the mid-1940's and the late 1960's (USGS, Hughes, J.L., 1977). The improvement observed in the mid-1940's is thought to be due to agricultural development of the Cuyama Valley that was supported by increased groundwater pumping in that Valley for irrigation. The increased pumping lowered groundwater levels in the Cuyama Valley, in turn reducing groundwater inflow to the Cuyama River, thereby reducing the contribution of dissolved salts (sulfate in particular) to the River.

The improvement observed in the late 1960's is thought to be due to implementation of Twitchell Reservoir project operations, which facilitated conservation of Cuyama River runoff and augmented recharge to the Santa Maria Valley groundwater basin. Specifically, the higher streamflow events in the Cuyama River that previously discharged to the ocean are of a better quality due to dilution by greater rainfall runoff. Releases from Twitchell Dam therefore contain lower concentrations of dissolved salts than the Cuyama River streamflows from the period preceding the project. The improvement in Cuyama River water quality from both of these developments may be seen in **Table 2.3-1**, which summarizes those earlier water quality results from the USGS (Hughes, J.L., 1977); more recent monitoring results from the USGS (1976 – 2019), the Central Coast Ambient Monitoring Program (CCAMP, CCRWQCB) (2000 – 2019), and the TMA (2017) are also shown.

Since operation of the Twitchell project began in the 1960s, Cuyama River water quality has remained fairly constant. Reported TDS values range from about 650 to 1,200 mg/L; sulfate and chloride concentrations range from 190 to 760 mg/L and from 25 to 85 mg/L, respectively. Nitrate-NO₃ concentrations have remained low, ranging from <1 to 20 mg/L.

Water quality in the Sisquoc River has remained relatively unchanged since 1906, with general mineral constituent concentrations typically below those observed in the Cuyama River. Since the Twitchell project began, reported TDS values have ranged from about 450 to 1,000 mg/L; sulfate and chloride concentrations have ranged from 270 to 380 mg/L, and from 13 to 16 mg/L, respectively. Nitrate-NO₃

concentrations have remained very low, ranging from <1 to 3.2 mg/L. Sisquoc River historical water quality is shown in a graph (**Figure 2.3-2a**), which in particular illustrates TDS values maintaining a long-term stability with slight seasonal variation, presumably due to varying stream discharge. Overall, the historical water quality data for the Sisquoc River and tributary streams indicate the quality of streamflows entering the Sisquoc plain are slightly improved by tributary inflows (Hughes, J.L., 1977).

As might be expected, water quality in the Santa Maria River northeast of Santa Maria (Bull Canyon) reflects the combined quality of streamflows in the Cuyama and Sisquoc Rivers. Reported TDS values have ranged from about 510 to 1,000 mg/L; sulfate concentrations have ranged from 180 to 540 mg/L; chloride values are about 25 mg/L; and nitrate-NO₃ concentrations have remained low, ranging from <1 to 2.7 mg/L.In contrast, water quality is degraded in streams in the western portion of the Santa Maria Valley, including the lower Santa Maria River and Oso Flaco Creek near Guadalupe. Reported TDS values have ranged from about 130 to 2,300 mg/L; sulfate concentrations have ranged from 440 to 1,000 mg/L (no chloride data are available), and nitrate-NO₃ concentrations have reached 450 mg/L. Water draining from Green Canyon, a canal coursing from the central valley floor toward Guadalupe to join the Orcutt Creek channel and ultimately the Santa Maria River, is of a similar quality.

Water quality is also degraded in streams in the southern portion of the SMVMA, including Bradley Canyon and Orcutt Creek, both of which drain the Solomon Hills. Bradley Canyon becomes the Bradley Channel as it travels northward draining about 5,700 acres of irrigated farmland in the eastern Santa Maria Valley. The drainage water has TDS values fluctuating between 180 and 1,300 mg/L and elevated nitrate concentrations reported as high as 150 mg/L (no sulfate or chloride data are available) (CCRWQCB, CCAMP, 2019). Orcutt Creek (at Black Road crossing) historical water quality, shown in a graph (**Figure 2.3-2b**), has TDS values typically fluctuating between 500 and 2,500 mg/L, with values that exceeded 3,600 mg/L in 2005 and 2006. During the last decade, nitrate concentrations typically exceeded the health-based standard of 45 mg/L, in fact exceeding 125 mg/L in 2007 through 2009 before declining to a range between 40 and 70 mg/L since 2011. Although the nitrate-NO₃ concentration in 2015 reached the highest observed for this portion of Orcutt Creek, 135 mg/L, the concentration was lowered substantially through 2019, to about 80 mg/L.

It should be noted that a trailer overturned on Highway 166 northeast of Santa Maria on March 21, 2020, resulting in the spill of 60 barrels of petroleum product with 4,600 gallons reaching the Cuyama River above Twitchell Reservoir (personal communication, T. Gibbons, April 3, 2020). State, Federal, County, and local emergency response teams and contractors responded to the spill and implemented cleanup and remediation activities to minimize or prevent the migration of petroleum constituents and product down the river to the reservoir. The SMVWCD retains involvement in operational oversight and, beginning in April, the CCRWQCB is providing additional remediation oversight.

2.4. Climate

The climatic data reported for the SMVMA are characterized in this section, specifically the current conditions in relation to historical trends in precipitation and evapotranspiration data.

2.4.1. Precipitation

At least three precipitation gauges have historically been located in the SMVMA, at Guadalupe, Santa Maria (currently at the Airport and previously downtown), and Garey (see **Appendix A, Figure 3**). Additional gauges include two operated by the Santa Barbara County Public Works Department at Sisquoc Ranch and Orcutt. The average annual rainfall measured at the Santa Maria Airport gauge, the most centrally located of the three gauges, is 12.65 inches. Historically, the majority of rainfall occurs during the months of November through April. In calendar year 2019, the total rainfall was above average at 17.10 inches, with the greatest monthly amounts in January through March and in December, as shown in **Table 2.4-1**.

Long-term rainfall characteristics for the SMVMA are reflected by the cumulative departure curve of historical annual precipitation (**Figure 2.4-1**), which indicates that the SMVMA has generally experienced periods of wetter than normal conditions alternating with periods of drier than normal to drought conditions. Wet conditions prevailed from the 1930's through 1944, followed by drier conditions from 1945 through the late 1960's. Subsequently, there have been shorter periods of alternating wet and dry conditions, including the most recent cycle of a wet period in the early-1990's to 1998, followed by the overall dry period from 2002 through 2019. Conditions have shown short-term variation with rainfall totals above the long-term average in 2010 and 2011 but well below the average since 2012.

The pattern of fluctuations in climatic conditions closely corresponds to the long-term fluctuations in groundwater levels described in Section 2.1.2 above, including the substantial decline observed between 1945 and the late 1960's and the subsequent repeating cycle of decline and recovery between historical-low and historical-high groundwater levels. Most recently, groundwater levels rose substantially in much of the SMVMA through 2011 in response to large amounts of rainfall in late 2010 and early 2011 (and the associated recharge from prolonged Twitchell Reservoir releases and high Sisquoc River discharge). However, the overall decline in groundwater levels observed since 2002 and particularly since 2012 was primarily attributed to the continued below average rainfall, Twitchell releases, and Sisquoc River discharge through 2016. The rainfall in 2017 was slightly above average, and the corresponding higher Sisquoc River streamflows and Twitchell releases contributed to substantial recovery of groundwater levels in 2017 into early 2018. The above average rainfall in 2019 likely contributed to slight additional recovery of groundwater levels through 2019.

2.4.2. Evapotranspiration

Three CIMIS climate stations were initially operated within the SMVMA for varying periods of time, specifically at Santa Maria, Betteravia, and Guadalupe between 1983 and 1997 (see **Appendix A, Figure 3**). Subsequently, CIMIS stations began operating near Sisquoc and on the southern Nipomo Mesa, the latter located just outside of the SMVMA, with climate data available for full calendar years beginning in 2001 and 2007, respectively. Most recently, a CIMIS climate station located on the floor of the Santa Maria Valley ("Santa Maria II" near the Santa Maria airport, see **Appendix A, Figure 3**) was reestablished in April 2011. A full calendar year of data from Santa Maria II was available for the first time in 2012. These six stations have recorded daily precipitation amounts, and all but Santa Maria II have recorded reference evapotranspiration (ETO), through present day. The latter station ceased recording the data in

2016 needed to estimate ETo, and the TMA is in the process of developing a replacement station on the Valley floor to provide precipitation and ETo data. Historically, annual ETo values ranged between 42 and 53 inches and averaged about 48 inches, as shown in a bar chart of the historical ETo values for the SMVMA (**Figure 2.4-2**).

Daily climate data for 2019 from the Santa Maria II, Nipomo, and Sisquoc stations are listed in **Table 2.4-2**, specifically daily, monthly, and annual ETo and precipitation amounts. Annual ETo values ranged from 43.30 inches (Nipomo) to 50.96 inches (Sisquoc). Evapotranspiration was highest during the months of June through August. The 2019 ETo values for the Santa Maria II station were estimated from the 2019 data from the Sisquoc and Nipomo CIMIS stations. Annual precipitation records appear to be poor for all CIMIS stations; none was recorded at the Sisquoc station and only about 13 inches were recorded at the other two stations, compared to the 17.10 inches reported at the Santa Maria Airport gauge. The possible reason for the poor quality of these CIMIS station precipitation records is being pursued with California DWR. As will be discussed in the following chapter, the 2019 estimated ETo values for the Santa Maria II station and the 2019 precipitation data from the airport gauge were utilized to estimate agricultural water requirements for the SMVMA in 2019.

3 WATER REQUIREMENTS AND WATER SUPPLIES

Current water requirements and water supplies in the SMVMA, including discussion of agricultural land use and crop water duties, which were the basis for estimation of agricultural water requirements and groundwater supply in 2019, are described in the following sections of this Chapter. Municipal water requirements and the components of water supply to meet those requirements, including groundwater and imported water from the State Water Project (SWP), are also described in the following sections.

The SMVMA 2018 crop acreages, which were not available at the time of the 2018 annual report, and the associated revised 2018 agricultural water requirements are provided in **Appendix C** of this 2019 annual report. The revised 2018 water requirements (from 2018 acreages now available, and 2018 crop water duties) are very similar to those estimated for the 2018 annual report (from 2017 acreages and 2018 crop water duties). Further, the revised 2018 water requirements are used herein for assessment of historical water requirements and supplies in this 2019 annual report.

3.1. Agricultural Water Requirements and Supplies

All agricultural water requirements in the SMVMA are supplied by local groundwater pumping, essentially all of which is neither directly metered nor otherwise indirectly measured. Consequently, agricultural water requirements, which represent by far the largest part of overall water requirements in the SMVMA, need to be indirectly estimated. Historically, and for this annual report, agricultural water requirements are estimated by quantifying land use (crop types and acreages), computing applied water requirements for each crop type, and summing total water requirements for the aggregate of various crops throughout the SMVMA. Reflected in this annual report are previously reported estimates of historical agricultural land use and water requirements through 1995 (LSCE, 2000), from 1998 through 2017 (LSCE, 2009 - 2018), as well as the revised 2018 estimate and the current estimate for 2019 made as part of the overall preparation of this annual report.

3.1.1. Land Use

An assessment was made of crop acreages in 2019 from the review of Pesticide Use Report (PUR) databases, including mapped agricultural parcels permitted for pesticide application, maintained by the Santa Barbara and San Luis Obispo County Agricultural Commissioner's Offices. The mapped parcels were identified by the respective Counties under the following crop types: 1) Rotational Vegetable, 2) Strawberry, 3) Wine Grape, 4) Pasture, 5) Grain, 6) Nursery, and 7) Orchard (Citrus and Deciduous). The acreage also accounted for hoop house crops (primarily the caneberries of raspberry and blackberry), hydroponic crops (primarily tomatoes), and cannabis (marijuana and hemp, specified as "Field" crop). Review of the PUR records indicated that "Rotational Vegetable" primarily consisted of lettuce, celery, broccoli, cauliflower, and spinach crops. Verification of agricultural cropland distribution in the SMVMA was conducted through review of 2019 satellite images, as well as 2018 color high-resolution (1 meter) aerial photographs available on a biennial basis (USDA National Agricultural Imagery Program, 2018) and a field spot check in fall 2019. An inventory of the images and photographs is also provided in **Appendix C** of this report. The distribution of irrigated acreage for 2019, by crop type identified by the Counties as well as by crop category utilized by the California DWR in its periodic land use studies, is listed in **Table**

3.1-1a. The crop parcel locations in 2019 are shown in a map of agricultural land use throughout the SMVMA (**Figure 3.1-1a**) and the distribution of historical irrigated acreage, including DWR land use study years and LSCE assessment years through 2019, is listed in **Table 3.1-1b** (USGS, Worts, G.F., 1951; California DWR, 1959, 1968, 1977, 1985, and 1995; LSCE, 2000 and 2009 - 2019).

In 2019, about 52,200 acres in the Santa Maria Valley were irrigated cropland, with the great majority (87 percent) in truck crops, from Rotational Vegetables (30,100 acres) and Strawberries (13,740 acres) to Hoop house crops (1,320 acres) and Hydroponic crops (170 acres). Vineyard comprised the next largest category (4,140 acres), with Pasture, Field, Nursery, Grain, and Orchard in descending order of acreage (from 440 to 70 acres). Fallow cropland was estimated to be approximately 1,560 acres. Cropland occupies large portions of the Santa Maria Valley floor, Orcutt Upland, Oso Flaco area, and Sisquoc plain and terraces.

The total irrigated acreage of about 52,200 acres in 2019 is within and near the upper end of the reported historical range of roughly 34,000 acres in 1945 to 53,000 acres in 1995 (see **Table 3.1-1b**). The 2019 cropland locations maintain the historical trend of agricultural expansion onto portions of the Orcutt Upland, Sisquoc Valley, and, most recently, Graciosa Canyon, as urban land use expands into former cropland near the central portions of the Santa Maria Valley and Orcutt Upland. Further, the crop type distribution continues the historical trend of increased truck crop acreage, including hoop house grown crops, and decline in pasture (including alfalfa), field, and orchard acreages, as illustrated by the bar chart of historical crop type distribution from DWR land use study years and for 2019 (**Figure 3.1-1b**). In order to provide consistency with the historical land use data, the crop acreages reported here are "land" acreages, i.e., the land area used for growing crops regardless of whether it is used for single or multiple cropping throughout any given year. Multiple cropping of land, and associated annual water requirements, is accommodated in the calculation of applied crop water requirements below.

3.1.2. Applied Crop Water Requirements

Applied crop water requirements were developed for the crop categories described above, and the approach used in their development depended on information available for each individual category. In the case of Rotational Vegetables (primarily lettuce, celery, broccoli, cauliflower, spinach, and bush berries), Strawberries, and Pasture, values for their evapotranspiration of applied water (ETaw) were developed using a CIMIS-based approach where reference evapotranspiration data (ETo) were coupled with crop coefficients (Kc) to first estimate the evapotranspirative water requirements of the crops (ETc). Those requirements were then factored to consider any effective precipitation in 2019 that would have reduced the need for applied water to meet the respective evapotranspirative water requirements, which in turn provided the ETaw values for those three categories.

For the remaining crop categories (except hoop house, hydroponic, and cannabis), for which information was insufficient to utilize a CIMIS-based approach, reported values of ETaw were used (California DWR, 1975). Specifically, these were values measured and developed for different rainfall zones in the central California coastal valleys, and a review of the reported values indicated that they accommodated multiple cropping. The values in turn had previously been used to develop a

relationship between ETaw values and the annual rainfall amounts within the Santa Maria Valley groundwater basin by crop type (LSCE, 2000). With a rainfall total of 17.10 inches in 2019 in the Valley, the previously developed ETaw values corresponding to that amount of precipitation were used for this assessment. For hoop house berries, an applied crop water duty was derived from local information on California central coast irrigation practices for hoop house berries, and from a publication on caneberry research conducted in California's central coast area (Bolda, et. al., October 2012). For hydroponic tomatoes, an applied crop water duty has been estimated from hydroponic crop research articles and notes (Selina, et. al., April 2002; Resh, 2005; and Jones, 2012). For cannabis crops, a reported applied crop water duty was utilized (Nelson, R.A., 2000).

For the three crop categories utilizing the CIMIS-based approach, the estimated 2019 ETo for Santa Maria II CIMIS station were used in conjunction with Kc values from the following sources to develop ETc values. The Rotational Vegetable value was based on reported values for lettuce derived from an agricultural reference for estimating ETc for vegetable crops (Univ. of California Cooperative Extension, 1994); the Strawberry values were derived from a paper reporting the results of a study on drip irrigation of strawberries in the Santa Maria Valley (Hanson, B., and Bendixen, W., 2004); and the Pasture values were directly based on the estimated ETo values for the reference surface (grass) at the Santa Maria II station. The resulting ETc values for the three crop categories are shown in **Table 3.1-1c**.

Effective precipitation (P_E) during 2019 was then subtracted from the ETc values to estimate crop ETaw values. The P_E amounts that contributed to meeting the ETc of the crops, and thus reduced applied water requirements, were based on review of the precipitation data for 2019, during which rain primarily occurred in January through March and in December. In 2019, precipitation met all or a portion of the ETc of the crops during those same months. It was assumed for the hoop house, hydroponic, and cannabis crops that no component of precipitation was effective. The calculated 2019 ETaw values for Rotational Vegetables, Strawberries, and Pasture, as well as the developed values for the remaining crop categories are shown in **Table 3.1-1c**.

Values of ETaw were then used to estimate applied crop water requirements (AW) by considering estimated irrigation system distribution uniformity (DU) values for each crop. For Strawberries grown in the Santa Maria Valley, DU values have been reported to range from 80 and 94 percent (Hanson, B., and Bendixen, W., 2004), and an intermediate DU value of 85 percent was selected for this assessment. For the remaining crops, DU values have not been specifically reported for the Santa Maria Valley; for this assessment, values of 80 percent (Rotational Vegetables, Truck, Grain, and Pasture), 85 percent (Citrus), and 95 percent (Vineyard, Nursery, and hoop house) were utilized. For the hydroponic tomato crops, all of which are grown in a controlled environment greenhouse, the DU value was assumed to be 100 percent. The resulting AW values for each of the crop categories are shown in **Table 3.1-1c**; they range in value as follows:

Highest water rate: 3.6 acre-feet per acre (af/ac) for pasture

Intermediate rates: 2.5 to 2.8 af/ac for deciduous/avocado and field (cannabis), 2.4 af/ac for rotational vegetables, and 2.0 af/ac for hoop house berries, hydroponic tomatoes, and nursery plants.

Lowest rates: 1.3 af/ac for strawberries, 0.9 af/ac for vineyard, and no irrigation for grain.

The AW values calculated for crops grown in the SMVMA are similar to those previously reported for crops grown in the NMMA (NMMA TG, 2009 through 2019). Between the two adjacent management areas, crops in common are Rotational Vegetables, Strawberries, Pasture, Citrus, Nursery, and Deciduous.

3.1.3. Total Agricultural Water Requirements

The AW values for each SMVMA crop category were coupled with their respective crop acreages to produce estimates of the individual crop and total agricultural water requirements, as shown in **Table 3.1-1c**. The resultant estimated total water requirement was 100,390 AF, with Rotational Vegetables comprising by far the greatest component, 73,350 AF, primarily because about 58 percent of the total acreage was dedicated to those crops. Strawberries comprised the next largest crop acreage and had an associated water requirement of 17,200 AF. Vineyard, hoop house berries, and pasture water requirements ranged from 3,920 AF down to 1,610 AF. All remaining crop types had water requirements at or below 700 AF.

In the context of historical estimates of total agricultural water requirements, the estimated 2019 agricultural water use is in the range of applied water requirements over the last four decades, as illustrated in a graph of historical irrigated acreage and agricultural groundwater pumping (the sole source of irrigation water in the Valley and, thus, equal to total agricultural water requirements) (**Figure 3.1-1c**). For reference, agricultural water requirements were previously estimated to be around 80,000 AFY during the 1940's and 1950's, gradually increasing to over 100,000 AFY by the 1970's; since then, agricultural water requirements have fluctuated from year to year, as a function of weather variability, but water requirements have generally remained within a broad but fairly constant range (LSCE, 2000, 2009 - 2019). Since the 1970's, maximum and minimum agricultural water requirements, respectively, were about 132,000 AF in 1997 and about 77,000 AF in 1998, with estimated agricultural water requirements in 2019 somewhat lower than those in 2018 (revised) and at about the middle of the historical range.

3.1.4. Agricultural Groundwater Pumping

As noted above, the sole source of water for agricultural irrigation in the SMVMA is groundwater, so groundwater pumping for agricultural irrigation in 2019 is of course estimated to be the same as the total estimated agricultural water requirement, 100,390 AF. This amount is midway within the historical range of estimated groundwater pumping for agricultural irrigation in the Valley over the last four decades. Proportions of groundwater pumping from the shallow and deep aquifer zones of the SMVMA are not known.

3.2. Municipal Water Requirements and Supplies

Prior to the late 1990's, all municipal water requirements in the SMVMA were met by local groundwater pumping. Since the beginning of State Water Project (SWP) availability in 1997, deliveries of SWP water have replaced some of the local groundwater pumping for municipal supply. Beginning in 2015 and

expanding since then, water (for municipal supply) was transferred from the SMVMA to the NMMA, discussed further in Section 4.4, by way of the recently constructed waterline intertie project. Municipal pumping, imported (SWP) water deliveries to the SMVMA, and intra-basin water transfers from the SMVMA to the NMMA are all metered; consequently, the following summaries of municipal water requirement and supplies derive from those measured data.

3.2.1. Municipal Groundwater Pumping

Municipal purveyors in the SMVMA include the Cities of Santa Maria and Guadalupe and the Golden State Water Company (GSWC, formerly Southern California Water Company, or SCWC). The latter provides water to suburban areas in the southern portion of the SMVMA, specifically the towns of Orcutt and Sisquoc and the Lake Marie and Tanglewood developments. With the exception of small pumping in Guadalupe and Sisquoc, municipal pumping is from numerous water supply wells in individual wellfields located between the Santa Maria Airport and the town of Orcutt. The municipal water supply wells are completed in the shallow and/or deep aquifer zones with, in general, newer wells having been constructed to produce from deeper portions of the aquifer system with better water quality. The monthly and annual groundwater pumping amounts for 2019 are tabulated by individual well, by purveyor, and for each water system in **Table 3.2-1a**.

In 2019, a total of 9,550 AF of groundwater was pumped for municipal water supply in the SMVMA, which is a decrease from the prior year (10,425 AF) but on the order of groundwater pumping reported for as long ago as the late 1960's. All purveyors pumped less groundwater in 2019 than in 2018. GSWC pumped the greatest amount, about 5,870 AF, with most of that for their Orcutt system and a minor amount for their other systems combined. The City of Santa Maria pumped about 3,110 AF and the City of Guadalupe pumped about 570 AF.

Since the initial deliveries of supplemental imported SWP water commenced in 1997, groundwater pumped for municipal supply has declined substantially, as shown in a graph of historical municipal groundwater pumping for the SMVMA (**Figure 3.2-1a**). The City of Santa Maria has greatly reduced pumping since the importation of SWP water began, from 12,800 AF in 1996 to an annual average of about 3,240 AF for subsequent years. In those years when pumping exceeds this annual average, it is typically due to limited SWP water availability. Such was the case recently in 2013 through 2015 when SWP water availability ranged from only 5 to 35 percent. The GSWC has also reduced groundwater pumping since the importation of SWP water began, from 9,960 AF in 1996 to an annual average of about 7,990 AF for subsequent years. Additionally, the City of Guadalupe has reduced groundwater pumping since the importation of SWP water began, from 725 AF in 1996 to an annual average of 660 AF for subsequent years. In 2019, purveyor pumping was less than their respective average annual amounts.

3.2.2. Imported Water

The three municipal purveyors in the SMVMA have entitlements to imported water from the SWP through the Central Coast Water Authority (CCWA). Each purveyor's total entitlement is comprised of their basic entitlement plus a "drought buffer" equal to 10 percent of their basic entitlement. By purveyor, their respective total entitlements are as follows: City of Santa Maria, 17,820 AF (16,200 AF basic entitlement plus 1,620 AF drought buffer); GSWC (SCWC), 550 AF (500 AF plus 50 AF drought buffer); and City of Guadalupe, 605 AF (550 AF basic plus 55 AF drought buffer). The drought buffer is intended to provide a way to stabilize annual fluctuations in SWP water deliveries to the purveyors due to annual fluctuations in SWP water availability, in essence firming up the overall reliability of the purveyors' SWP entitlements. As such, during years when SWP water availability exceeds purveyor demand, unused entitlement allocations could be stored either directly into a groundwater basin or in an in-lieu manner (i.e. exchange with other SWP Contractors). Conversely, during years when SWP water availability is less than purveyor demand, stored entitlement water or returned exchange water is meant to be available to augment SWP deliveries (personal communication, S. Springer, City of Santa Maria, April 26, 2016).

The total entitlements listed in Exhibit F to the Stipulation are as follows: Santa Maria, 17,800 AF; GSWC (SCWC), 550 AF; and Guadalupe, 610 AF. The amounts listed for Santa Maria and Guadalupe appear to be the actual entitlements described above but "rounded off." Such as the Stipulation also specifies certain minimum importation of SWP water, as a function of its availability in any given year and also as a function of individual purveyor entitlement, the following assessment of imported water use in 2019 is related to those total entitlements.

In 2019, total deliveries of SWP water to the SMVMA were 10,350 AF, more than those of the previous year (9,875 AF). The majority of those deliveries, 9,850 AF, were to the City of Santa Maria. A portion of the Santa Maria deliveries, about 370 AF, was transferred to GSWC. GSWC also took delivery of 15 AF of its own entitlement, for a total of about 385 AF, and the City of Guadalupe took delivery of 480 AF of its entitlement. The monthly and total annual deliveries of SWP water to the SMVMA in 2019 are summarized in **Table 3.2-1b**.

Historically, municipal deliveries commenced in 1997 with approximately 4,500 AF going to the City of Santa Maria. The following year, the City's delivery more than doubled to nearly 10,700 AF and GSWC took about 80 AF (the City of Guadalupe delivery records prior to 2004 are unavailable). Over the entire period since SWP water deliveries to the SMVMA began, the average total annual amount delivered is 10,300 AFY, and the average SWP water availability is 64 percent. California's highly variable climatic conditions can be seen from review of the historical SWP water deliveries (and percent SWP water availabilities) for the SMVMA: delivery amounts have ranged from 13,780 AF in 2006 (SWP availability of 100 percent) to 1,770 AF in 2014 (SWP availability of 5 percent). The effect of the recent extended dry period can also be seen: the average annual SWP availability during the period 2008 through 2019 is only 46 percent, compared to the average for the preceding years, 81 percent, as can be seen in a graph of historical SWP water deliveries to the SMVMA (**Figure 3.2-1b**).

As mentioned above, the Stipulation designates minimum amounts of SWP water to be imported and used in the SMVMA in any year as a function of individual entitlement and SWP availability. Santa Maria is to import and use not less than 10,000 AFY of available SWP water, or the full amount of available SWP water when it is less than 10,000 AF. GSWC is to import and use all its available SWP water. Guadalupe is to import and use a minimum of 75 percent of its available SWP water. In 2019, overall SWP water availability was 75 percent of entitlements. So, for municipal purveyors in the SMVMA, that availability converts to the following individual availability of SWP water: Santa Maria, 13,350 AF (10,000 AF minimum); GSWC, 410 AF; and Guadalupe, 460 AF (75 percent of which, or 340 AF, as a minimum was to be imported). Actual imports of SWP water by all three municipal purveyors, including the transfers from Santa Maria to GSWC (within the SMVMA) and to the NMMA (intra-basin), were as follows: Santa Maria, 9,860 AF; GSWC, 385 AF (including 370 AF from Santa Maria); and Guadalupe, 480 AF (see **Table 3.2-1b**). Comparison of these figures indicates Santa Maria and GSWC imported slightly less than their respective minimum amounts specified in the Stipulation; Guadalupe imported slightly more. The following summarizes SWP availability and purveyor imports in 2019:

- 10,350 AF total was imported by the three purveyors
- 9,630 AF of the total imported was utilized in the SMVMA

3.2.3. <u>Total Municipal Water Requirements</u>

Total municipal water requirements in 2019 were about 19,900 including the approximate 960 AF of water transferred by Santa Maria to the NMMA; the total water utilized within the SMVMA was then 18,940 AF. The 2019 total water requirements are slightly less than in 2018 and are on par with the requirements as far back in time as the mid- to late 1980's. The 2019 total reflects an overall stability in municipal water use since 1989, prior to which a steep increasing trend was observed (particularly 1970 – 1989). The overall history of municipal water use in the SMVMA is detailed in Table 3.2-1c and illustrated in a graph of annual municipal requirements (**Figure 3.2-1c**).

3.3. Total Water Requirements and Supplies

The total water requirement (combined agricultural and municipal) in 2019 for the SMVMA, including the water provided by intra-basin transfer from the SMVMA to the NMMA, was approximately 120,285 AF, as seen in **Table 3.3-1a**.

In 2019, the total demand was met almost entirely by groundwater pumping, about 109,935 AF, which is less than the total groundwater pumping for the previous year (about 120,080 AF). The balance of the total demand was roughly 10,350 AF met by delivery of imported water from the SWP. This amount is more than the total imported water to the SMVMA for the previous year (9,875 AF) and the long-term average delivery from 1997 through 2019 (10,300 AFY).

Groundwater pumping in 2019 met 100 percent of the agricultural water requirement (100,390 AF), 48 percent of the municipal water requirements (9,550 of 19,900 AF), and about 91 percent of the total water requirements for the SMVMA, including the NMMA transfer (109,940 of 120,285 AF).

Historical total water requirements in the SMVMA have increased from about 80,000 AF in 1950 to about 150,000 AF by 1990, and have fluctuated in a broad but relatively constant range between about 100,000 and 150,000 AFY, as shown in a graph of historical total water requirements (**Figure 3.3-1**). Total water requirements in 2019 remained within that range.

Historical water supplies in the SMVMA were solely derived from groundwater pumping until 1997, when the City of Santa Maria commenced importation of SWP water. While groundwater has always met 100 percent of agricultural water requirements, since 1997 groundwater has met a wide range of municipal water requirements, from 35 to 92 percent. Further, groundwater has comprised a consistently large portion of the total water requirements in the SMVMA (from 87 to 99 percent), as shown in **Table 3.3-1b**.

Over the period since SWP water deliveries began in the SMVMA, the average total annual amount delivered is 10,300 AFY, and the average SWP water availability is 64 percent. In contrast, during the recent extended dry period, the average annual SWP delivery amount from 2008 through 2019 is 8,920 AFY with an average SWP availability of only 46 percent. Historical SWP water deliveries (and percent SWP water availabilities) range from 13,780 AF in 2006 (SWP availability of 100 percent) to 1,770 AF in 2014 (SWP availability of 5 percent).

4 WATER DISPOSITION

The Stipulation directs that there be an annual accounting of the disposition of water supplies in the SMVMA. The primary uses of water in the SMVMA are for agricultural irrigation and for domestic and related municipal uses, as detailed in Chapter 3, where most of the water is consumptively used. The balance of water supply primarily **deep-percolates**, or is disposed, back to the groundwater basin via the following pathways: 1) deep percolation of applied irrigation that exceeds agricultural crop water requirements, 2) deep percolation of landscape or other non-agricultural irrigation, 3) purposeful infiltration of treated municipal waste water, and 4) in the Sisquoc Valley, deep percolation of a very minor amount of water treated in septic systems.

Other disposition of water in the SMVMA includes purposeful **consumptive use** of treated municipal waste water via spray irrigation for disposal (evapotranspiration); additional losses derive from treatment sludge disposal and brine injection from reverse osmosis treatment. In some years, treated water is consumed in off-site industrial or commercial uses. Lastly, in the Sisquoc Valley, very minor amounts of water are lost during septic system treatment. Additional disposition of water is agricultural drainage in localized areas, specifically those of low soil and aquifer permeability and shallow groundwater levels, and water transfer from the SMVMA to the NMMA per provisions of the Stipulation.

4.1. Agricultural Return Flows

The largest component of overall return flows in the SMVMA originates as applied water for agricultural irrigation. Except for local areas near the Santa Maria River toward the western end of the SMVMA, where subsurface drainage removes shallow groundwater beneath irrigated lands, applied irrigation in excess of crop water requirements is considered to deep percolate beyond crop rooting depths and result in return flows to groundwater. The estimation of agricultural water requirements and associated groundwater pumping, as described in Section 3.1, is based on crop areas, respective crop water requirements, and estimated performance of various irrigation systems. Most crops in the SMVMA are considered to consumptively use 80 to 85 percent of the water applied to them, resulting in the balance of 20 to 15 percent, respectively, exceeding crop consumption and deep percolating (as return flow) to the underlying aquifer system. This includes cannabis, considered as a field crop, recently introduced to the SMVMA. Exceptions to the preceding ranges are wine grapes and hoop house berries, where 95% of applied water is estimated to be consumptively used (resulting in a return flow of 5% of applied water). Lastly, for hydroponic tomatoes, 100% of applied water is estimated to be consumptively used.

For the full range of crop categories in the SMVMA, return flow rates in 2019 are estimated to range from 0.10 af/ac or less for vineyard and hoop house berries, to 0.4 to 0.5 af/ac for the predominant rotational vegetables and orchard, to a maximum of about 0.72 af/ac for pasture. The respective estimated agricultural return flow rates are detailed in **Table 4.1-1**. When combined with their respective individual crop acreages, it is estimated that, in 2019, about 18,150 AF of the 100,390 AF of applied agricultural irrigation became return flows to the SMVMA aquifer system.

4.2. Municipal Return Flows

Municipal return flows primarily derive from the discharge of treated waste water generated at three municipal waste water treatment plants in the SMVMA (with a very minor amount derived from septic systems in the Sisquoc Valley). Additional return flows derive from the application of landscape irrigation within the service areas of the three main water purveyors of the SMVMA. The estimation of these municipal return flows is described below.

The three municipal waste water treatment plants in the SMVMA are as follows: the City of Santa Maria plant located west of the City; the Laguna CSD plant west of the Santa Maria Airport; and the City of Guadalupe plant west of Guadalupe (see **Appendix A, Figure 2a**). At the City of Santa Maria WWTP, influent volumes are metered and recorded, and all treated water is discharged to percolation ponds near Green Canyon adjacent to the plant facilities. At the Laguna CSD WWTP, influent volumes are metered and recorded water is discharged to permanent spray fields north and west of the plant facilities and to Santa Maria airport lands for irrigation (with winter discharges to storage ponds). In 2019, a minor amount of effluent was provided for industrial use, specifically for dust control and soil compaction in the SMVMA. At the City of Guadalupe WWTP, influent volumes are recorded, and all treated water is discharged to permanent spray fields north of the plant facilities, across the Santa Maria River (with discharge to a storage pond north of the facility).

The monthly total influent data from 2019 are shown by facility and method of disposal in **Table 4.2-1**. For the Cities of Santa Maria and Guadalupe plants, effluent volumes are estimated to be 90 percent of the metered influent, with the remainder assumed to be lost (consumed) during treatment. For the Laguna CSD, effluent volumes are calculated as the balance of the recorded influent minus sludge and brine volumes. In 2019, a total estimated 9,500 AF of treated municipal waste water were discharged in the SMVMA. About 72 percent (6,850 AF) of that total was discharged to the percolation ponds of the City of Santa Maria WWTP. Approximately 21 percent (2,000 AF) of the total treated water was discharged by Laguna CSD to spray irrigation of the WWTP permanent pasture and Santa Maria airport lands, and by the City of Guadalupe to spray irrigation. The balance of seven percent (about 600 AF) of the total treated water remained in storage or went to commercial use.

The Stipulation has provisions for each of the municipal water purveyors in the SMVMA to have rights to recover return flows (by pumping "commingled groundwater") that derive from their respective importations of water from the SWP. Those rights are to specific fractions of SWP water use in the preceding year; they are limited in time to recovery in the following year, and thus do not carry over or otherwise accumulate in the basin. The Stipulation designates their respective fractions as 65 percent for Santa Maria and 45 percent each for GSWC (formerly Southern California Water Company) and for Guadalupe. The Stipulation is silent as to the basis for the respective fractions; logically, however, they would have some basis in the fate of imported SWP water, i.e. what fraction ends up being "disposed" as a "return flow" to the groundwater basin.

Since the SMVMA water supply is a commingled combination of groundwater and SWP water, the "return flow" fraction attributable to SWP water would be the same as that for the commingled supply. An accounting of waste stream volumes from the different sources as influent to the three WWTPs and the calculated return flows generated from the WWTP discharge for years 1997 through 2019 are provided in **Table 4.2-2**. Return flows derived from landscape irrigation within the SMVMA urban areas (water applied beyond the consumptive use of landscape plantings) are also included in **Table 4.2-2**. The supporting calculations of return flows from WWTP discharge (for 1997 forward) and landscape irrigation (from 2008 forward) are provided in **Appendices D and E**, respectively.

While the volume of influent is recorded at each of the three WWTPs, the amount of water toward landscape irrigation is necessarily estimated. The monthly base indoor water usage is assumed to approximately equal the reported water supply for the winter months, with water use in excess of that base amount for all other months calculated as landscape irrigation. The balance of water supplies (i.e., not conveyed to WWTPs or utilized for landscape irrigation) is assumed to have been consumptively used or lost during conveyance in water service areas. The results of these calculations provide an indication of the fate of water used by the cities of Santa Maria and Guadalupe and by the GSWC. Specifically, the fate and approximate average percentage of each purveyor's respective water supplies are as follows (See **Appendix E**, 2008 forward):

- WWTP total influent/water supply: Santa Maria, 68%; GSWC, 33%; Guadalupe, 74%
- Landscape irrigation/water supply: Santa Maria, 28%; GSWC, 44%; Guadalupe, 18%
- Residential consumption and conveyance loss/water supply: Santa Maria, 4%; GSWC, 23%; Guadalupe, 8%

Interpretation of the Santa Maria municipal water supply and waste water processes, as well as the estimated return flows from WWTPs and landscape irrigation, indicates the average fraction of return flows to water supply for the period from 1997 through present is 66 percent. Thus, the 65 percent "return flow" fraction specified in the Stipulation for Santa Maria is representative of the amount of Santa Maria water supply providing return flow to the SMVMA. This is primarily the case because the great majority of waste water generated in Santa Maria is conveyed to the City's WWTP (with some small amount conveyed to the Laguna CSD WWTP) where effluent discharge is to percolation ponds for purposeful infiltration (and generation of return flows) to the groundwater basin (see **Table 4.2-2**).

Interpretation of the GSWC/Laguna CSD and Guadalupe water supplies and waste water processes, as well as the estimated return flows from WWTPs and landscape irrigation, indicates their average fractions of return flows to water supplies for 1997 through the present are 18 and 16 percent, respectively. Thus, it appears the 45 percent "return flow" fraction specified in the Stipulation for GSWC and Guadalupe is not representative of the amount of their respective water supplies providing return flow to the SMVMA. Additional assessment of the SWP water use and disposition within the GSWC service areas, including interconnections with facilities of the City of Santa Maria and Laguna CSD, will be addressed in subsequent annual reports. However, estimated return flows for GSWC and Guadalupe can be expected to be lower than Santa Maria because the great majority of their waste water is

conveyed to treatment plants where effluent discharge is primarily to permanent spray fields for evapotranspiration, with only minor generation of return flows to the groundwater basin.

4.3. Agricultural Drainage

In areas of low soil and aquifer permeability and shallow groundwater levels, such as the Oso Flaco Valley, agricultural irrigation water in excess of crop water requirements percolates past the crop root zone to provide return flows to the aquifer or to be intercepted by area drains before reaching the aquifer. Further, the return flows to the aquifer increase water in storage in the aquifer and raise shallow groundwater levels; in certain cases, this rise in groundwater levels can be sufficiently high for area drains to capture and drain groundwater from the aquifer.

While no known measurements exist of the agricultural drainage that recently occurred in the SMVMA, a local study provides information about the timing and amounts of drainage in several portions of Oso Flaco Creek during 2010, 2011, and early 2012 (Althouse and Meade, Inc., October 2012). From this information, specifically the reported monthly mean discharge (in cubic feet per second (cfs)) at a portion of the Creek immediately upstream from Oso Flaco Lake, an estimate was made of the total annual agricultural drainage in 2010 and 2011. Discharge at this point was considered to represent the total drainage of the area, including the agricultural drainage and the surface water runoff associated with rain events. The discharge measured during the dry months of each year, specifically May through October, was considered to be comprised solely of agricultural drainage with no contribution of surface water runoff from rain. During 2010, the monthly mean discharge rates for May through October were similar and averaged 6.5833 cfs, and during 2011, the monthly mean discharge rates for May through October were also similar and averaged 5.8750 cfs. These rates were assumed to represent the agricultural drainage that occurred during all months of each year and were utilized to estimate annual agricultural drainage, approximately 4,800 AF in 2010 and 4,300 AF in 2011, or an average of about 4,500 AFY.

In the SMVMA 2014 annual report (LSCE, April 2015), in order to estimate agricultural drainage in the area during 2014, consideration was made of the depth to groundwater and the period of seasonal agricultural irrigation during 2010, 2011, and 2014. While area groundwater levels were slightly lower in 2014 than in 2010/2011 (and thus would be expected to contribute less groundwater to drainage ditches and Oso Flaco Creek), it appears that the irrigation season began earlier and was longer in 2014 than in 2010/2011 (and thus would be expected to contribute more intercepted water to drainage ditches and the Creek). Each of these factors was assumed to offset each other and, for that reason, the average discharge of 4,500 AFY was used as an estimate of the agricultural drainage in 2014.

Recent Oso Flaco area groundwater depths and agricultural irrigation are similar to those in 2014; as such, the average discharge of 4,500 AFY was used as an estimate of the agricultural drainage in 2019.

4.4. Intra-Basin Water Transfer

The Stipulation includes provisions specific to the NMMA for implementation of a Memorandum of Understanding (MOU) between the City of Santa Maria and the Nipomo CSD to provide for the sale of a

minimum of 2,500 AF of "supplemental water" per year by the City to Nipomo CSD. That sale for delivery of water constitutes an intra-basin water transfer within the Santa Maria Groundwater Basin from the SMVMA to the NMMA.

In support of the sale, an agreement was approved between the City and Nipomo CSD that serves as a successor to the MOU (Wholesale Water Supply Agreement or "Agreement") and facilities were completed with the capacity to convey 500 to 1,000 AFY of water from the SMVMA to the NMMA ("Phase I" Waterline Intertie Project or WIP). The Agreement and WIP accommodate future project expansion such that water deliveries are planned as follows: 645 af in year one; 800 AFY in years 2 through 5; 1,000 afy in years 6 through 10, and 2,500 afy in years 11 through the term of the agreement (2085). A provision in the Agreement specifies that the Nipomo CSD may request delivery of an additional 3,200 afy in excess of these quantities (potential total delivery of 5,700 afy).

The intra-basin transfer of water from the SMVMA to the NMMA commenced in July 2015, with the delivery of about 50 af of water in each month from July through December. Thus, in the latter half of 2015, a total of 314 af of water was transferred. Delivery of an additional 337 af of water was completed in the first half of 2016, thus delivering a total of about 650 af of water in year one of the Agreement (directly on par with the Agreement amounts). Water transfers to the NMMA in 2016 (calendar year) totaled 770 af. Transfers in calendar years 2017 through 2019 increased to about 970 af (960 af in 2019).

The water transfers beginning in 2015 have reduced the amount of groundwater pumping of the NCSD, one goal of the Stipulation provision regarding such transfer. With the City's importation of SWP water (and continued water conservation efforts), the water transfer to the NMMA in 2019 was conducted without increasing the City's groundwater pumping from the SMVMA beyond early 1970s levels. As such, benefits to the basin from SWP water importation included reduced groundwater pumping for municipal supply and an improved water quality supply.

Further, the City's water demand for the SMVMA (excluding the additional demand to meet intra-basin transfers) is currently projected to increase from about 12,200 af in 2015 to about 14,500 af in 2030, and then to about 16,200 af by 2040 (City of Santa Maria, April 2016). Importantly, this projection of water demand is lower than previous projections due to the fact recent conservation efforts of the City and its customers have resulted in substantially lower per capita water use. Specifically, per capita water use has decreased from over 200 gallons per day (GPD) before 1990 to less than 110 GPD in 2015. This was apparent in the City's 2015 water demand, which was about 10 percent lower than the previous year and essentially in the range of the mid- to late 1980's. The City's water demand since then has remained within that lower range, and water conservation (not the acquisition of additional SWP entitlement) has met and even exceeded the City's additional demand specific to intra-basin water transfer.

5 CONCLUSIONS AND RECOMMENDATIONS

Conclusions drawn from assessment of the hydrogeologic conditions and the water requirements, supplies, and disposition in the SMVMA in 2019 are discussed in the following section, which is in turn followed by recommendations regarding enhanced groundwater recharge and expansion of the SMVMA monitoring program.

5.1. Conclusions

5.1.1. <u>Hydrogeologic Conditions</u>

Assessment of hydrogeologic conditions in 2019 showed that groundwater levels were similar to or higher than those in 2018 (with one localized exception in the Twitchell Recharge Area), and the water levels and general mineral quality in the shallow and deep aquifer zones remain within historical ranges for the SMVMA. As has historically been the case for several decades, the prevailing gradients for groundwater flow in both zones was reduced (flattened) in the vicinity of local pumping near the Santa Maria Airport, but groundwater flow continued through the area toward the coast where groundwater levels remained above sea level. In the last few years during the fall period, including in 2019, a portion of the offshore groundwater flow in the shallow and deep aquifer zones appears to flow to the northwest beneath the southern coastal Nipomo Mesa, with eventual capture by pumping wells or offshore flow from the Mesa.

Nitrate concentrations remain elevated in the shallow aquifer zone of the SMVMA, with the exception of the Coastal Area where nitrate levels remain at or below detection limits, including in 2019. Nitrate concentrations remain stable near or below detection limits in the deep aquifer zone of the SMVMA. The exceptions to this are portions of the Municipal Wellfield and the north Coastal Area (200 to 500 feet deep) where gradual increases in nitrate levels in some deep wells have continued through 2019.

Operation of Twitchell Reservoir has, overall, continued to provide conservation of runoff for subsequent release for groundwater recharge in the SMVMA, despite sedimentation that has now filled the former dead pool storage below the conservation pool of the Reservoir. With precipitation well below average from 2012 through 2016, Twitchell Reservoir storage and releases were essentially nil and discharge in the Sisquoc River was well below average during that recent period. More recently, the rainfall amounts in 2017 and 2019 were above average, as were Sisquoc River discharge (2017 and 2019) and Twitchell releases (2017).

General mineral and nitrate concentrations remain elevated in streams in the western and southern portion of the SMVMA, including the Santa Maria River, Oso Flaco Creek, and Green Canyon near Guadalupe, as well as Orcutt Creek and Bradley Canyon on the Orcutt Upland. In comparison, the Cuyama, Sisquoc, and Santa Maria Rivers in or flowing into the eastern portion of the SMVMA have only slightly elevated salt levels and very low levels of nitrate. In the case of all the main streams, the reported constituent concentrations in 2019 were within their respective historical ranges.

5.1.2. <u>Water Requirements, Supplies, and Disposition</u>

Total water requirements for the SMVMA in 2019 were less than the previous year (120,285 and 129,960 af, respectively). The water requirements for agricultural irrigation in 2019 compared to the previous year were 100,390 and 109,660 af, respectively. Municipal water requirements in 2019 and 2018 were 19,900 and 20,300 af, respectively. Regarding total water supplies in 2019 compared to the previous year, imported SWP water deliveries were increased (10,350 and 9,875 af, respectively) as was the SWP availability (75 and 35 percent, respectively), while total groundwater pumping decreased (109,940 and 120,080 af, respectively). Regarding the disposition of the total water used in 2019 compared to the previous year, the consumptive use of water and return flows were stable. Water transfer to the NMMA in 2019 was essentially the same as the previous year (960 and 970 af, respectively), with the generated return flows benefiting the basin as a whole. Water requirements, supplies, and disposition in the SMVMA during 2019 are summarized in **Table 5.1-1**.

Regarding agricultural land and water use in 2019, the total irrigated acreage and crop distribution were very similar to the previous year with plantings devoted primarily to truck crops. The associated applied water requirement was less than in the previous year but consistent with the generally constant trend in agricultural land and water use in the SMVMA over the last 20 years. Specifically, total irrigated cropland has been stable between 48,000 and 53,000 acres, with increased truck crop acreage and a decline in pasture, field, and citrus acreages. The associated applied water requirements have also been stable, although in the broad range of 80,000 to 120,000 afy that is largely driven by year-to-year weather conditions. In 2019, the sole source of water supply for agricultural irrigation continued to be groundwater and, thus, agricultural groundwater pumping equaled the agricultural water requirement. Disposition of the agricultural irrigation was to evapotranspiration by crops (76,600 af), return flow to the groundwater basin (19,300 af), and drainage captured in the Oso Flaco Valley area, specifically in drainage ditches and Oso Flaco Creek (4,500 af).

Regarding municipal water requirements and supplies in 2019, the total water requirement was less than in the previous year and consistent with the long-term trend for the SMVMA. Specifically, municipal water demand over the last 30 years has been fairly stable within a broad range of 19,000 to almost 26,000 afy. The total municipal water requirement in 2019 was met by a blend of groundwater and SWP water (48 and 52 percent, respectively). The 2019 groundwater pumping was lower than the previous year but on par with groundwater pumping reported for as long ago as the early 1970's. The 2019 SWP water delivery and the long-term average delivery over the period 1997 – 2019 was greater than the previous year. SWP water availability was higher than in the previous year (75 and 35 percent, respectively) and the long-term average availability remained the same (64 percent over 1997 – 2019). Importantly, in 2019, SWP water deliveries to the SMVMA water purveyors were essentially on par with minimum annual amounts specified in the Stipulation.

Disposition of municipal water supply in 2019 was very similar to the last 10 to 15 years. A large portion of the total municipal water supply, 8,515 af, was utilized in municipal service areas, either consumptively used or generating return flow from landscape irrigation (in the Sisquoc water service area, consumptive use and return flows also derive from septic systems). Most of the remaining

municipal supply, about 10,420 af, became influent to WWTPs, and the treated water was consumptively used or generated return flows from surface spreading in infiltration basins and spray irrigation. The remainder of municipal supply, about 960 af, was transferred from the SMVMA to the NMMA to augment Nipomo CSD water supply per Stipulation provisions.

5.1.3. <u>Stipulation</u>

The November 21, 2012, California Court of Appeal decision preserved the Stipulation provisions for each of the municipal purveyors in the SMVMA awarding rights to return flows derived from purveyors' respective importations of SWP water. At that time, appellants did not challenge the respective return flow percentages and, accordingly, the decision does not address their accuracy. However, current technical analysis, as described in this and previous annual reports, indicates the existing systems for waste water treatment and disposal are such that only the City of Santa Maria discharges in a manner that supports the 65 percent return flow fraction specified in the Stipulation for the City. Waste water treatment and disposal of waters supplied by GSWC and the City of Guadalupe are estimated to be roughly one-half the 45 percent return flow fraction specified in the Stipulation for them.

Finally, the Stipulation delineates four specific criteria that, when all are met in any given year, define a condition of severe water shortage in the SMVMA; those four criteria are:

- chronic decline in groundwater levels (over period of not less than 5 years);
- groundwater levels below lowest recorded levels;
- groundwater level decline not caused by drought; and
- material increase in groundwater use during the five-year period.

While groundwater levels in the SMVMA gradually declined overall since about 2002, they remain in 2019 above the lowest recorded levels in the great majority of the SMVMA. Drier conditions prevailed through the period from 2002 through 2016, notably resulting in no releases from Twitchell Reservoir in 2002 through 2004, 2007, 2009, 2010, and 2013 through 2016, with only limited releases in most intervening years. Also of note during this dry period were the greatly reduced streamflows in the Sisquoc River. Thus, the gradual decline in groundwater levels through 2016 was most likely attributable to drought conditions. Rainfall, Sisquoc River discharge, and Twitchell releases were near or above average in 2017 and 2019, and groundwater levels remained the same or rose during this recent period with continued Twitchell releases in late 2017, early to mid-2018, and all of 2019. Importantly, the total groundwater use in 2019, at 109,940 af, was comparable to use during the last 15 years, which has ranged between 90,000 and 135,000 afy. In summary, conditions in the SMVMA do not satisfy all the criteria delineated in the Stipulation for defining a severe water shortage; as a result, it is concluded that there is no finding of severe water shortage conditions in the SMVMA in 2019.

5.2. Recommendations

Recommendations related to the hydrogeologic conditions and water supply in the SMVMA include the enhancement of groundwater recharge and expansion of the SMVMA monitoring program, as discussed herein.

Enhancement of Groundwater Recharge

The amount of groundwater pumped for municipal water supply in the SMVMA in 2019 remained substantially lower than during the last two decades. This reduction in groundwater pumping is certainly due to SWP water importation but also very likely due to recent conservation efforts. While it is unknown to what extent water conservation in the agricultural industry has reduced groundwater pumping over time, the continued conservation of water on the part of both municipal and agricultural interests would clearly benefit the maintenance of SMVMA groundwater levels.

Augmentation of groundwater recharge projects could alleviate, to a certain extent, groundwater level declines in the SMVMA in the short and long term. Further, with the existing ground and surface water quality degradation in the SMVMA, the implementation or expansion of certain water resource management approaches could reduce the contribution of salts, nutrients, and other constituents of concern to ground and surface water. Thus, it is recommended that activities that enhance groundwater recharge, including its quality, be developed further. Toward this goal are the following examples:

- Agricultural landowners and operators have implemented water quality monitoring and management programs (under the Irrigated Lands Regulatory Program) that reduce agricultural runoff, constituent loading to surface waters, and salt loading to groundwaters of the SMVMA;
- The Laguna CSD typically provides a small amount of treated water for industrial or commercial uses, effectively recycling water that, in turn, reduces groundwater pumping by that amount; and
- The SMVWCD, in collaboration with the TMA, has completed studies and plans to conduct a stream infiltration enhancement project along portions of the Santa Maria River. Completion of the project would facilitate increased stream recharge to the aquifer and improved groundwater quality.

Expansion of the SMVMA Monitoring Program

With the cessation of USGS groundwater level monitoring, and reduction in groundwater quality sampling, beginning in 2019 for the SMVMA, the current collaborative plan (SMVWCD and TMA) to maintain groundwater level measurements is crucial for continued groundwater conditions assessment. It is recommended that:

- Beyond the current arrangements for the April 2020 measurements (in the SMVWCD well network and USGS well subset), a long-term arrangement or understanding be finalized between the SMVWCD and TMA to ensure continued measurements in the future;
- The USGS well subset be evaluated for improvement after the April measurements, such as to replace or add wells as needed; and
- A USGS well subset for groundwater quality sampling be developed and implemented as early as summer/fall 2020, including to address areal and vertical well coverage for water quality sampling.

Since the adoption of the SMVMA Monitoring Program, its implementation has proceeded in phases, and it is recommended that efforts in areas besides groundwater continue. Priorities for existing monitoring needs, include:

- Implementation of stream discharge gauging, in order of priority: 1) Cuyama River (below Twitchell), 2) Sisquoc River tributaries (Foxen, La Brea, and Tepusquet Creeks), and 3) Santa Maria River tributaries (Nipomo and Suey Creeks); and
- Installation of or development of access to at least: 1) one shallow well east of Orcutt and 2) one deep well northwest of the City of Santa Maria, for inclusion in the monitoring program well networks.

In 2019, work was also completed, and progress made, to expand monitoring in the SMVMA:

• Completed:

Measurement of groundwater levels in fall 2019 made in 16 USGS wells typically measured only in the spring, by formal arrangement between the SMVWCD and TMA, and

Maintenance of the two new (replacement) pressure transducers in shallow wells at the SMVMA: NMMA boundary, with collection in fall 2019 of the daily water level data.

• Work in progress:

Installation of a CIMIS station on the Santa Maria Valley floor at the City of Santa Maria Well 10 site (to replace Santa Maria II station).

1) Total effluent estimated as 90% of metered influent (assumed loss of 10% during treatment); all effluent discharged to ponds.

2) Total effluent estimated as approx. 95.5% of metered influent, the balance from influent minus sludge and brine treatment losses; effluent to storage reservoir and discharged to spray field irrigation, dust control.

3) Total effluent estimated as 90% of metered influent; all effluent discharged to spray field irrigation.

4) Includes spray irrigation on Laguna Sanitation District fields and irrigation on Santa Maria airport lands.

5) For industrial use, primarily dust control in SMVMA.

6) Cumulative reservoir storage allows monthly irrigation and dust control uses to exceed monthly discharge to reservoir.

Estimated

SM City of Santa Maria

GSWC Golden State Water Company

Guad City of Guadalupe

LSD Laguna Sanitation District

1) Excludes Sisquoc System water use (for effluent return flow calculations).

2) Range of SM total water supply used for landscape irrigation estimated from monthly water use data since 2008 (App E) = 20 - 35%

3) Range of GSWC total water supply used for landscape irrigation estimated from monthly water use data since 2008 (App E) = 28 - 55%

4) Range of Guad total water supply used for landscape irrigation estimated from monthly water use data since 2008 (app E) = 10 - 28%

5) All effluent from Santa Maria WWTP percolation ponds assumed as return flows.

6) 20 percent of effluent from Laguna San and Guadalupe WWTP spray irrigation assumed as return flows.

7) 20 percent of landscape irrigation assumed as return flows.

I. INTRODUCTION

The terms and conditions of a Stipulation in the Santa Maria Valley Groundwater Basin Litigation passed down by the Superior Court of the State of California, County of Santa Clara, on June 30, 2005, are intended to "impose a physical solution establishing a legal and practical means for ensuring the Basin's long-term sustainability." Under the Stipulation, the groundwater, imported and developed water, and storage space of the Basin are to be managed in three management areas, including one for the Santa Maria Valley (SMVMA) (Figure 1). The management area is approximately 175 square miles in size encompassing the Santa Maria and Sisquoc Valleys, extending north to the Nipomo Mesa, east to the cliffs above the Santa Maria River and terraces along the Sisquoc River, south to the Casmalia and Solomon Hills, and west to the coast.

According to the Stipulation, a monitoring program is to be established for each of the three management areas to collect and analyze data regarding water supply and demand such that the following objectives are met:

- 1) assessment of groundwater conditions, both levels and quality;
- 2) determination of land use, water requirements, and water supply; and
- 3) accounting of amounts and methods of disposition of water utilized.

This monitoring program has been prepared to meet these objectives in the SMVMA. Also in accordance with the Stipulation, it is expected that the monitoring results will be utilized for preparation of annual reports on the SMVMA, including an assessment of whether conditions of severe water shortage are present. The monitoring program for the SMVMA, with minor revisions from October 2008, is described by individual element in the following section.

Among other components, the monitoring program includes networks of historically monitored wells, stream gauges, and climatic stations. These monitoring points were selected based on publicly available information about their locations, characteristics, and historical data records with the intent of continuing those records as much as possible. It is recognized that, as implementation of the program proceeds, the inclusion of some network wells may be determined to be impractical or impossible due to problems of access or abandonment. Further, the reestablishment of inactive (or installation of new) wells, stream gauges and climatic stations will depend on interagency coordination, permitting procedures, and budgetary constraints. Thus, it is anticipated that the overall monitoring program will be incrementally implemented as practicalities like those mentioned above dictate. Similarly, it is expected that, with time, the program will undergo modification in response to various factors (e.g. replacing network wells abandoned in the future, revising well classifications by aquifer depth zone), while maintaining the overall goal of facilitating interpretation and reporting on water requirements, water supplies, and the state of groundwater conditions in the SMVMA.

II. MONITORING PROGRAM

As a basis for designing the monitoring program, all pertinent historical data on the geology and water resources of the SMVMA were updated and compiled into a Geographic Information System (GIS). The data include the following:

- well location, reference point elevation (RPE), depth, and construction information;
- surface water gauge locations and characteristics;
- precipitation gauge and climate station locations and characteristics;
- groundwater levels and quality;
- Twitchell Reservoir releases, stream discharge and quality;
- precipitation and reference evapotranspiration (ETo) records;
- topographic, cultural, soils, and land use maps;
- geologic map and geologic structure contours;
- water purveyor wellfield areas;
- wastewater treatment plant (WWTP) locations.

The GIS was first utilized to define aquifer depth zones for groundwater monitoring purposes. In the central and major portion of the SMVMA, there is a shallow zone comprised of the Quaternary Alluvium, Orcutt formation, and uppermost Paso Robles formation and a deep zone comprised of the remaining Paso Robles formation and Careaga Sand. In the eastern portion of the SMVMA where these formations are much thinner and comprised of coarser materials, particularly in the Sisquoc Valley, the aquifer system is essentially uniform without distinct aquifer depth zones. In the coastal area where the surficial deposits (upper members of Quaternary Alluvium and Orcutt formation) are extremely fine-grained, the underlying formations (lower members of Quaternary Alluvium and Orcutt formation, Paso Robles formation, and Careaga Sand) comprise a confined aquifer.

The GIS was then used to classify a majority of wells into the shallow or deep aquifer zones based on well depth and completion information, although a number of wells could not be classified because this information is either unavailable or indicates completion across both the shallow and deep zones. An evaluation was made of the distribution of wells across the SMVMA completed in each depth zone. Wells actively or historically monitored for water levels and quality by the U.S. Geological Survey (USGS) and its cooperating local agencies¹ (Agencies) were identified, and an evaluation was made of the adequacy of coverage of the SMVMA to meet the objective in the Stipulation of assessing groundwater conditions.

It was determined that the wells actively monitored by the Agencies for groundwater levels provide extensive but somewhat incomplete coverage of the SMVMA, with areas

¹ Cooperating local agencies include Santa Barbara County, San Luis Obispo County, and the Santa Maria Valley Water Conservation District (SMVWCD).

left unmonitored in both aquifer zones. Based on this assessment, the groundwater monitoring program for the SMVMA was designed to first incorporate all of the actively monitored wells (denoted herein as "active wells"). Thus, those wells will continue to be monitored for water levels by the Agencies with the resulting data used toward assessing groundwater conditions in the SMVMA.

Secondly, in order to fill the gaps in coverage around the active wells, the groundwater monitoring program includes a number of additional wells historically monitored by the Agencies that are no longer monitored (denoted herein as "inactive wells", but intended to be actively monitored as part of this program). Thus, water level monitoring in these wells will need to be restarted in collaboration with the Agencies. This will provide the additional benefit of bringing forward the historical water level records of the inactive wells, some of which begin in the 1920s.

Regarding the active and inactive wells, those that could not be classified by aquifer depth zone (noted as "unclassified wells") are nonetheless included in the monitoring program because they contribute to completing well coverage of the SMVMA. The main revision to the October 2008 monitoring program is classification of previously unclassified wells based on additional well information, water level, and water quality data collected since the monitoring program was implemented.

Third, the groundwater monitoring program includes new monitoring wells to be installed in both the shallow and deep aquifer zones in an area north of downtown Santa Maria to fill a gap in coverage by existing wells. Arrangements will need to be made for the well installations, and monitoring will need to be implemented in collaboration with the Agencies.

This groundwater monitoring program designates a subset of wells for the purpose of monitoring groundwater quality, with well selection based on evaluation of well depths, completion information, and historical water level and quality data. It was determined that, of those wells actively monitored for groundwater levels, very few are actively monitored for groundwater quality. The subset of groundwater quality wells under this monitoring program incorporates the few active water quality wells, which will continue to be monitored for water quality and wells historically monitored for water levels (but no longer) monitored for water quality and wells historically monitoring in these wells will need to be restarted or implemented in collaboration with the Agencies. Lastly, in order to fill a gap in coverage by existing wells, the new monitoring well to be installed in the deep aquifer zone north of downtown Santa Maria is included in the subset of groundwater quality wells.

Thus, the groundwater monitoring program designates two well networks, one each for the shallow and deep aquifer zones, primarily comprised of wells that are actively monitored. The networks include additional wells that are currently inactive (monitoring to be restarted) and some new wells (installation and monitoring to be implemented). All network wells are to be monitored for groundwater levels, with a subset of those wells to be monitored for groundwater quality, as described in detail in the subsection below.

Another use of the GIS was for the evaluation of actively and historically monitored surface water and climatic gauges by their location and period of record, specifically for Twitchell Reservoir releases, stream discharge, precipitation, and reference evapotranspiration (ETo) data, in order to assess adequacy of coverage in the SMVMA to meet monitoring objectives in the Stipulation. In this case, it was determined that the actively monitored gauges provide a substantial but incomplete accounting of surface water resources in the SMVMA, with several streams no longer monitored and the Valley floor without any climatic gauges. The SMVMA monitoring program was designed to incorporate the active gauges and reestablish inactive gauges to provide a comprehensive record of surface water and climatic data. A revision to the October 2008 monitoring program is the addition of a surface water sampling point on Green Canyon drainage, currently monitored for flow and quality.

A description of the groundwater, surface water, and climatic monitoring included in the SMVMA monitoring program is provided in the following subsection. Three monitoring program elements designate the data collection to be conducted across the area including 1) hydrologic data with which groundwater conditions, surface water conditions, and agricultural water requirements may be assessed, 2) water requirements and supply data for agricultural irrigation and municipal use; and 3) water disposition data for agricultural and municipal land uses.

2.1 Hydrologic Data

Hydrologic data include groundwater levels and quality from two well networks, one each for the shallow and deep aquifer zones. Also to be collected are data on Twitchell Reservoir releases and stream stage, discharge, and quality, from a designated set of surface water monitoring locations. The data also include precipitation and ETo data, which will be used to estimate agricultural water use in the SMVMA.

2.1.1 Groundwater Levels and Quality

Well Networks

Evaluation of historical groundwater level and quality data from the SMVMA indicates that groundwater conditions differ across the area and with depth; accordingly and as described above, the groundwater monitoring program designates both shallow and deep well networks. The monitoring networks include along the coast three sets of existing grouped monitoring wells that are completed at varying depths for the purpose of detecting conditions of saltwater intrusion. However, the networks lack coverage inland in an area north of downtown Santa Maria adjacent to the Santa Maria River, necessitating the installation of at least one shallow and one deep well.

The monitoring networks are primarily comprised of wells actively monitored by the USGS and cooperating agencies (Agencies). The networks include additional wells that are currently inactive (monitoring to be restarted) and some new wells (installation and monitoring to be implemented). The shallow well network consists of 68 wells for groundwater level monitoring with a subset of 37 wells for water quality monitoring (Table 1a and Figure 2a), including one new well to be installed north of Santa Maria and monitored for shallow groundwater levels. The deep well network consists of 52 wells for water level monitoring with a subset of 38 water quality wells (Table 1b and Figure 2b), including one new well to be monitored for groundwater levels and quality in the deep zone. In addition, 29 unclassified wells are included for groundwater level monitoring with a subset of 4 water quality wells (Table 1c); they are shown on both the shallow and deep well network maps (see Figures 2a/2b) to illustrate the areal distribution of network wells across the SMVMA.

To augment the monitoring program results, data from water supply well monitoring conducted by the Cities of Santa Maria and Guadalupe and by the Golden State Water Company to meet California Dept. of Health Services requirements will be compiled. Likewise, data from sanitation facility well monitoring conducted under their respective permit conditions will augment the monitoring program results. Finally, data collected from wells in the Nipomo Mesa Management Area (NMMA) monitoring program (not part of the SMVMA well networks) will be compiled in order to assess groundwater conditions in the area along the northern boundary of the SMVMA.

Overall, the groundwater monitoring networks for the SMVMA include:

- 149 wells for water levels (68 shallow, 52 deep, 29 unclassified), of which:
- 91 of the 149 wells are active (42 shallow, 28 deep, 21 unclassified) and will continue to be monitored for water levels by the Agencies,
- 56 wells are inactive (25 shallow, 23 deep, 8 unclassified) and will need to have water level monitoring restarted in collaboration with the Agencies,
- 2 wells are new (1 shallow and 1 deep) and will need to have arrangements made for their installation and water level monitoring implemented in collaboration with the Agencies, and
- 79 of the 149 wells are also for water quality (37 shallow, 38 deep, 4 unclassified), of which:
- 14 wells are active (4 shallow, 9 deep, 1 unclassified), and will continue to be monitored for water quality by the Agencies,
- 34 wells are inactive (17 shallow, 14 deep, 3 unclassified), and will need to have water quality monitoring restarted in collaboration with the Agencies,
- 30 wells not monitored (16 shallow, 14 deep), and will need to have water quality monitoring implemented in collaboration with the Agencies,
- 1 well is new (deep) and will need to have water quality monitoring implemented in collaboration with the Agencies.

The areal coverage of wells for groundwater levels and quality is comparable to previous groundwater resources investigations periodically conducted by the USGS. The groundwater monitoring networks are comprehensive and conservative in that they provide areal coverage of the SMVMA in two depth zones, including focused monitoring for potential saltwater intrusion along the coast. Upon implementation of the groundwater monitoring program and analysis of the initial groundwater level and quality results, an assessment will be made of whether the well network requires modification, e.g., more or less wells, while ensuring the monitoring objectives of the Stipulation are met.

Monitoring Specifications

Under the monitoring program, groundwater level measurements in each network well will be made from an established wellhead reference point to an accuracy of 0.01 foot. Groundwater quality monitoring will include general mineral constituents to facilitate description of the general groundwater chemistry throughout the SMVMA. In addition, specific inorganic constituents are included to assess effects of historical and current land uses and groundwater quality relative to potential saltwater intrusion along the coast. The initial monitoring constituents for both the shallow and deep well networks are:

General Minerals (including Total Dissolved Solids (TDS), Electrical Conductivity (EC), pH, sodium (Na), calcium (Ca), magnesium (Mg), potassium (K), chloride (Cl), sulfate (SO4), and bicarbonate (HCO3)
Nitrate as Nitrate (NO3-NO3)
Bromide (Br)

All sample collection, preservation, and transport will be according to accepted EPA protocol. Sample analyses are to be conducted by laboratories certified by the State of California utilizing standard EPA methodologies. Analyses for NO3-NO3 and Br are to achieve minimum reporting limits of 0.10 mg/l.

The great majority of existing wells in the SMVMA have reported reference point elevations (RPEs) that appear to have been derived from USGS 7-1/2' topographic quadrangles, with variable levels of accuracy. Therefore, a wellhead survey will need to be conducted establishing the RPE for each network well to an accuracy of less than one foot, preferably to 0.01 foot, in order to allow accurate assessment of groundwater conditions throughout the SMVMA. The wellhead survey would most easily be completed using survey-grade global positioning system (GPS) equipment. Upon evaluation of the initial monitoring results, an assessment will be made regarding the need to verify RPEs or modify the set of water quality constituents and/or reporting limits.

Monitoring Frequency

Historical groundwater level data from the SMVMA indicate that water levels typically peak between January and April and decline to the seasonal low between July and October. Accordingly, the initial frequency of groundwater level monitoring is semiannually during the spring and fall, as has typically been the practice of the USGS and some cooperating agencies.

Review of historical groundwater quality data indicates that some quality constituents, such as sulfate, nitrate, and associated TDS and EC values, can change substantially over two to three years. As a result, the initial frequency of groundwater quality sampling is every two years, and preferably during the summer to allow any necessary followup sampling. Coastal monitoring wells will be sampled twice annually, during spring and fall, to evaluate seasonal water quality changes with the seasonal fluctuation in Valley groundwater levels.

The annual groundwater level and quality monitoring results from purveyors and sanitation facility wells will be compiled with the results from the SMVMA monitoring program, at which time an assessment will be made regarding the need for additional monitoring of selected purveyor/facility wells. Regarding the SMVMA well network, following evaluation of the initial groundwater level and quality results, an assessment will be made whether monitoring frequencies need to be modified.

Data Sources, Agency Coordination, and Plan Implementation

Implementation of the groundwater monitoring program will necessitate completing several tasks augmenting the groundwater monitoring currently conducted by the Agencies. It is recommended that program implementation proceed through the following tasks in order:

1) Coordination with the Agencies (primarily the USGS) and landowners to assess site conditions at each designated program well, including field determinations of well and wellhead conditions and access (as needed), with the objective of establishing final well networks (shallow and deep) for the ongoing measurement of water levels and collection of water quality samples;

2) Installation of monitoring wells in those areas lacking coverage by the established networks;

3) Coordination with the Agencies and landowners to make arrangements for conducting groundwater level and quality monitoring, per the monitoring program, on an ongoing basis; and

4) Completion of a wellhead survey to record the reference point elevation and ground surface elevation at each network well.

On an annual basis, the designated groundwater monitoring activities for the SMVMA will need to be coordinated with the USGS and cooperating agencies to confirm their continued monitoring of network wells. During each year, groundwater level and quality data from the Agencies will be compiled with the SMVMA dataset, and an assessment will be made of the remaining data needs to fulfill the groundwater monitoring program. The annual agency coordination, planning of monitoring activities, data collection, and data compilation will be jointly conducted by LSCE and the TMA.

2.1.2 Surface Water Storage, Discharge, Stage, and Quality

Monitoring Locations

Twitchell Reservoir stage, storage, and surface water releases are recorded on a daily basis. Also, four stream gauges in the SMVMA currently provide average daily discharge data, specifically two on the Sisquoc River ("near Sisquoc" and "near Garey"), one on the Santa Maria River ("at Suey Crossing near Santa Maria"), and one on Orcutt Creek ("near Orcutt"). Together, the reservoir release data and current stream gauge measurements account for the primary components of streamflow into the Santa Maria Valley (Figure 3).

Additional data are needed for the main streams associated with the Santa Maria Valley for the purpose of assessing surface water resources and stream/aquifer interactions in the SMVMA. The main component of streamflow into the Santa Maria Valley is not measured, specifically from the Cuyama River (inactive gauge), and streamflow from the Santa Maria Valley cannot be accounted because the gauge located on the Santa Maria River at Guadalupe is inactive. Further, for all streams in the SMVMA, stage measurements are not reported and water quality monitoring is limited to the Sisquoc River ("near Sisquoc") and Orcutt Creek ("near Orcutt"). A sampling point on Green Canyon provides information on the flow and quality of drainage in the western Valley.

Accordingly, the surface water monitoring program specifies that reservoir stage, storage, and releases from the Twitchell Project continue to be recorded on a daily basis. The program also designates a set of stream gauges on the Sisquoc, Cuyama, and Santa Maria Rivers and Orcutt Creek for the determination of average daily stage and discharge (see Figure 3). Gauge locations will serve as water quality sampling points. Additional water quality sampling points (without gauge) are the current Green Canyon point and a new one to be located on Oso Flaco Creek.

The main surface water monitoring locations for the SMVMA include:

- Twitchell Project, which will continue to be monitored for reservoir stage, storage, and releases (with water quality monitoring to be implemented) by the SMVWCD;
- 6 stream gauges, of which:
 2 gauges will continue to be monitored for stream discharge and quality by the USGS:

"Sisquoc River near Sisquoc"

"Orcutt Creek near Orcutt"

2 gauges will continue to be monitored for stream discharge by the USGS (with water quality monitoring to be implemented in collaboration with the USGS):

"Sisquoc River near Garey"

"Santa Maria River at Suey Crossing near Santa Maria"

2 gauges for which stream discharge and water quality monitoring will need to be reestablished in collaboration with the USGS:

"Cuyama River below Twitchell"

"Santa Maria River at Guadalupe"; and

• Green Canyon, for which flow and quality monitoring will continue, and Oso Flaco Creek, for which water quality monitoring will need to be implemented in collaboration with the USGS.

The inactive gauges on the Cuyama River ("below Twitchell) and Santa Maria River ("at Guadalupe") need to be reestablished, and rating curves relating stage measurements to discharge need to be redeveloped. If possible, it would be preferable to establish an alternate location for the Cuyama River gauge closer to its confluence with the Sisquoc River. At the present time, streamflow entering the Santa Maria Valley from the Cuyama River can be estimated from Twitchell Project release data (streamflow losses occur on the Cuyama River between Twitchell Dam and its confluence with the Sisquoc River). Streamflow data from the former Cuyama River gauge facilitated better estimation of streamflow entering the Valley but did not preclude estimation errors.

Operation of the Santa Maria River gauge at Suey Crossing, located in the primary recharge area of the River, will need evaluation. Currently, stream discharge data are reported only sporadically; it appears that stage data have been collected but not yet converted to discharge pending development by the USGS of appropriate rating curves. However, data collection may be being compromised by technical problems with the gauge, in which case timely resolution of the problems or consideration of an alternate gauge location in this reach of the River would be necessary.

It should be noted that, in order to provide for the most complete assessment of surface water resources of the SMVMA, data would also be needed for its tributary streams. Streamflows into the Sisquoc Valley from La Brea Ck, Tepusquet Ck, and Foxen Canyon cannot be accounted because their respective gauges are inactive. Also, streamflows into the Santa Maria Valley from Nipomo and Suey Creeks have not been monitored (see Figure 3). Thus, stream gauges for the determination of average daily stage and discharge would need to be reestablished for La Brea, Tepusquet, and Foxen Canyon Creeks and installed on Nipomo and Suey Creeks in collaboration with the USGS.

To augment the surface water monitoring program results, water quality data from stream studies periodically conducted by the Central Coast Regional Water Quality Control Board and from sanitation facility monitoring will be compiled.

Monitoring Specifications

For the Twitchell Project, reservoir stage will need to be related to storage volume. For all stream gauges, stage measurements will need to be reported relative to some known elevation datum. Under the monitoring program, initial surface water quality analyses to be performed are for the same general mineral and specific inorganic constituents as for groundwater. Reservoir and stream sample collection will be according to accepted protocol; sample preservation, transport, analyses, and reporting limits will be according to groundwater quality monitoring specifications.

Monitoring Frequency

For the Twitchell Project, daily releases and reservoir stage are to be recorded. For all streams, gauge operations will provide average daily stream stage and discharge data. Water quality monitoring will be conducted on a semi-annual basis during the period of maximum winter/spring runoff and minimum summer flows to evaluate changes in surface water quality with fluctuations in stream discharge.

Data Sources, Agency Coordination, and Plan Implementation

Implementation of the surface water monitoring program will necessitate completing several tasks augmenting the stream monitoring currently conducted by the USGS. It is recommended that program implementation proceed through the following tasks in order:

1) Coordination with the USGS to assess site suitability for stream gauges on the Cuyama River ("below Twitchell") and Santa Maria River ("at Guadalupe"), with the objective of establishing the locations and specifications for gauge installation to conduct ongoing measurement of stream stage, discharge, and quality;

2) Coordination with the USGS to install stream gauges and develop rating curves for the Cuyama River ("below Twitchell") and Santa Maria River ("at Guadalupe") locations;

3) Coordination with the Agencies to make arrangements for conducting surface water monitoring, per the monitoring program, on an ongoing basis on the designated streams (USGS) and Twitchell Reservoir (SMVWCD);

4) Coordination with the USGS to assess site suitability for stream gauges on the tributaries La Brea, Tepusquet, Foxen Canyon, Suey, and Nipomo Creeks, with the objective of establishing the locations and specifications for gauge installation to conduct ongoing measurement of stream stage, discharge, and quality;

5) Coordination with the USGS to install stream gauges and develop rating curves for the La Brea, Tepusquet, Foxen Canyon, Suey, and Nipomo Creeks locations; and

6) Coordination with the Agencies to make arrangements for conducting surface water monitoring, per the monitoring program, on an ongoing basis on the designated streams and tributaries (USGS) and Twitchell Reservoir (SMVWCD).

On an annual basis, the designated surface water monitoring activities for the SMVMA will need to be coordinated with the USGS to confirm their continued operation of each monitoring program gauge. During each year, Twitchell Project data from the SMVWCD will be compiled with stream stage, discharge, and water quality data from the USGS. Annual agency coordination, planning of monitoring activities, data collection, and data compilation will be jointly conducted by LSCE and the TMA.

2.1.3 Precipitation and Reference Evapotranspiration (ETo)

Monitoring Locations

There currently are three active NCDC² precipitation gauges in the SMVMA providing long-term daily precipitation data through the present, specifically at Guadalupe, the Santa Maria airport (formerly downtown), and Garey. In addition, daily precipitation is recorded at four locations around the SMVMA, at the Twitchell Dam (by the SMVWCD) and three active CIMIS³ climate stations on the Santa Maria Valley floor, near Sisquoc, and on the southern Nipomo Mesa. Daily ETo data are also currently recorded by these three CIMIS climate stations (see Figure 3).

Accordingly, the monitoring program designates the set of four active precipitation gauges (NCDC and Twitchell) and three active CIMIS climate stations for the determination of daily precipitation and ETo (see Figure 3).

The climatic monitoring stations include:

- Four precipitation gauges, which will continue to be monitored by current operators: Twitchell Dam (SMVWCD) Guadalupe (NCDC) Santa Maria Airport (NCDC) Garey (NCDC)
- Three climate stations for precipitation and ETo, which will continue to be monitored by California DWR:

'Santa Maria II' 'Sisquoc' 'Nipomo'

² NCDC: National Climatic Data Center, administered by the National Oceanic and Atmospheric Administration (NOAA).

³ CIMIS: California Irrigation Management Information System, administered by California Department of Water Resources (California DWR).

Monitoring Specifications and Frequency

Precipitation gauges will continue to collect total daily precipitation data, and climate stations will report daily ETo values. Operation of the climate stations will be according to CIMIS standards to collect all data utilized in the calculation of ETo values (e.g., air temperature, relative humidity, air speed).

Data Sources, Agency Coordination, and Plan Implementation

On an annual basis, the designated climatic monitoring activities for the SMVMA will need to be coordinated with the NCDC, California DWR, and SMVWCD to confirm their continued operation of each gauge/station. The annual coordination with these agencies and data compilation will be jointly conducted by LSCE and the TMA.

2.2 Water Requirements and Supply Data

These data include agricultural land use derived from land use surveys as input to the estimation of applied agricultural water requirements and, thus, groundwater pumping (sole supply) in the SMVMA. Data also include municipal and private purveyor records of water supplies, which include groundwater and imported water that in total equal the municipal water requirements in the SMVMA.

2.2.1 Agricultural Land Use and Water Requirements

Under the monitoring program, land use surveys of the SMVMA will be conducted on an annual basis from analysis and field verification of aerial photography. In the event that aerial photographs of the SMVMA are unavailable from existing agricultural service companies, arrangements for the aerial photography work will need to be made.

Survey results will be utilized to determine crop distribution and acreages, which in turn will be used in conjunction with standard crop coefficient values, ETo and precipitation data, and Valley-specific irrigation efficiency values to estimate annual applied agricultural water requirements. With groundwater serving as the sole source of water supply for agricultural irrigation in the SMVMA, the estimated applied agricultural water requirements will be considered equal to the agricultural groundwater pumping in the SMVMA.

Aerial photography arrangements and analysis, field verification, determination of crop distribution and acreages, and estimation of agricultural water requirements will be jointly conducted by LSCE and the TMA.

2.2.2 Municipal Water Requirements

As part of the monitoring program, records will be compiled of groundwater pumping and imported water deliveries from the State Water Project, Central Coast Authority (SWP), to municipal and private water purveyors, including the Cities of Santa Maria and Guadalupe, and the Golden State Water Company. All data will be recorded by subsystem on a monthly basis; groundwater pumping will be by individual water supply well; and all water transfers within the SMVMA between purveyors are to be noted. Also included are data on the number of service connections, any estimates of water usage on a per capita or per connection basis, and historical and current projections of water demand.

During the first year, purveyors will also provide current service area boundaries and all available water supply well location, depth, and completion information. With groundwater pumping and imported water deliveries as the two sources of water supply for municipal water use in the SMVMA, their total will be considered equal to the municipal water requirements in the SMVMA.

During each year, water supply data from the purveyors will be compiled into the SMVMA dataset. Annual coordination with purveyors will be jointly conducted by LSCE and the TMA.

2.2.3 Groundwater Pumping

The estimated groundwater pumping for agricultural irrigation will be summed with the reported pumping for municipal use in order to calculate total annual groundwater pumping in the SMVMA.

2.2.4 Imported Water

Imported water data will be obtained to summarize SWP deliveries to municipal and private water purveyors, specifically the Cities of Santa Maria and Guadalupe and the Golden State Water Company. Those data will be summed to calculate total annual imported water supplies in the SMVMA.

2.3 Water Disposition Data

In order to provide an accounting of amounts and methods of disposition of water utilized in the SMVMA, several data are to be reported. These include treated water volumes processed and disposed at wastewater treatment plants (WWTPs); records of any water exported from the SMVMA; and estimates of agricultural drainage disposed outside the SMVMA. "Disposition" of applied irrigation not consumptively used by crops, e.g., return flows to the aquifer system, will also be accounted.

2.3.1 Treated Water Discharge

Under the monitoring program, records of influent and treated effluent volumes will be compiled for WWTPs, including the Cities of Santa Maria, Guadalupe, and Laguna Sanitation District. All data will initially be recorded on a monthly basis to assess seasonal variation in the disposition of water (e.g., percentage of water utilized that becomes WWTP influent; losses during treatment). Effluent volumes will be recorded by disposal method and location, including any reuse of recycled water.

These data will be utilized to provide an accounting of municipal water disposed in the SMVMA. During each year, water disposal data from the WWTPs will be compiled into the SMVMA dataset. Annual coordination with the WWTPs will be jointly conducted by LSCE and the TMA.

2.3.2 Exported Water

As part of the monitoring program, records will be compiled of any groundwater or imported (SWP) water that is exported from the SMVMA. All data will be recorded by subsystem on a monthly basis and the receiving entities are to be noted. During each year, the data acquisition and compilation into the SMVMA dataset will be jointly conducted by LSCE and the TMA.

2.3.3 Agricultural Drainage and Return Flows

Under the monitoring program, estimation will be made of water drained from agricultural fields (e.g., by tile drains) for disposal outside of the SMVMA. Finally, while not formally "monitored," the disposition of applied irrigation will include estimates of the fate of that fraction of water not consumptively used by crops, primarily as return flow to the aquifer system.

III. SUMMARY

The monitoring program for the SMVMA includes the collection of hydrologic data, including: groundwater levels and quality; surface water storage, stream stage, discharge, and quality; and precipitation and ETo. The program provides designated shallow and deep well networks (Tables 1a/b/c and Figures 2a/b) and a surface water and climatic monitoring network (Figure 3) for collection of these data. Also specified are water requirements and supply data to be compiled for agricultural irrigation and municipal use, the disposal data for municipal water use, data on water exported from the SMVMA, and estimates of agricultural drainage and return flows.

The monitoring program components and frequencies are summarized as follows:

- groundwater levels: 149 wells (68 shallow, 52 deep, 29 unclassified), of which:
 91 wells are actively monitored (with monitoring to continue),
 56 wells are inactive (with monitoring to be reactivated), and
 2 wells are new (with monitoring to be implemented);
 semiannual frequency.
- groundwater quality: subset of 79 wells (37 shallow, 38 deep, 4 unclassified); of which:
 - 14 wells are actively monitored (with monitoring to continue),
 - 34 wells are inactive (with monitoring to be reactivated),
 - 30 wells are unmonitored and
 - 1 well is new (with monitoring to be implemented;

analyzed for General Minerals (incl. NO3-NO3) and Bromide; biennial frequency.

 Twitchell Reservoir: stage, storage, and releases, which are actively monitored (with monitoring to continue), and quality, which is unmonitored (with monitoring to be implemented); stage, storage, and releases monitored daily;
 quality analyzed for General Minerals (incl. NO3. NO3) and Bromide on a

quality analyzed for General Minerals (incl. NO3-NO3) and Bromide on a biennial frequency.

- streams: 6 designated gauges for discharge, stage, and quality, of which:
 - 2 gauges are actively monitored for discharge and quality (to be continued),
 - 2 gauges are actively monitored for discharge (to be continued) but not monitored for water quality (to be implemented), and
 - 2 gauges are inactive (discharge and water quality monitoring to be reestablished);

discharge and stage monitored daily;

quality analyzed for General Minerals (incl. NO3-NO3) and Bromide on a biennial frequency.

- stream tributaries: 5 potential gauges for daily discharge and stage, that are inactive and would need to be reestablished.
- precipitation: 4 active gauges (to be continued); daily frequency.
- ETo: 3 active stations (to be continued); daily frequency.
- land use; annually.
- municipal water requirements, supplies (groundwater pumping and SWP imported water), disposal, and exportation; monthly.
- agricultural drainage and return flow; annually.

Estimated

| SM | City of Santa Maria | Santa Maria | Avg Percentage, Influent/Water Use = | 67.0 % |
|------|----------------------------|-------------|--------------------------------------|--------|
| GSWC | Golden State Water Company | GSWC | Avg Percentage, Influent/Water Use = | 31.9 % |
| Guad | City of Guadalupe | Guadalupe | Avg Percentage, Influent/Water Use = | 67.4 % |
| LSD | Laguna Sanitation District | | | |

1) For Santa Maria, water transfers to NMMA began in 2015, but are excluded for SMVMA return flow calculations; for GSWC, all years, excludes Sisquoc system water use (typically 40 - 70 afy) for SMVMA effluent return flow calculations. 2) For 1997 - 2011, influent amount of 95 afy from Santa Maria to LSD WWTP estimated (LSD staff, April 2009); for subsequent years, reported influent amount of 100 afy (LSD staff, April 2012 and April 2016).

3) For 1997 - 1998, percentage of SM total water use as total influent to WWTPs estimated as 65.5% (SM staff, April 2009).

4) For 1997 - 1999, percentage of GSWC water use (excluding Sisquoc System) as total influent to WWTPs estimated as 31.5%.
5) For 1997 - 2007, percentage of Guadalupe total water use as influent to WWTP estimated as 60% (Guad staff, April 2009).

6) Includes industrial use (oil lease) and dust control; no return flows generated.

7) Reservoir for storage only, no return flows generated.

8) For 1997 - 2011, effluent volumes available for generating return flows from GSWC-derived wastewater at LSD WWTP adjusted (from previous annual reports) to reflect zero return flows from brine injection and industrial use. 9) GSWC return flow amounts from LSD WWTP, total return flow amounts, and % water use reflect effluent volume adjustments described in footnotes 4 and 8.
