## 5 **INTRODUCTION**

6 Groundwater surface elevations (GSE) underlying the Nipomo Mesa are regularly  
7 measured at many places (wells) across the mesa. Hydrographs from individual wells provide  
8 a temporal record of the GSE measurements at one location. Presented herein is the Spring 2008  
9 GWS estimate along with estimates of historical annual variability in GWS from 1975 to 2007  
10 based on groundwater surface elevation measurements collected during Spring and Fall across  
11 the Nipomo Mesa. Limited measurements of GSE were available for the years 1982, 1983, 1984,  
12 1994 and 1997, thus precluding a reliable estimate of GWS for those years.

## 14 **RESULTS**

15 Estimated Spring 2008 GWS is 83,000 acre-feet (AF), 17,000 AF greater than Fall 2007, but  
16 10,000 AF lower than Spring 2007 (Table 1, Figure 1). Estimates of the GWS metric have  
17 dropped approximately 10,000 AF in each of the last two consecutive years.

## 19 **METHODOLOGY**

20 The annual estimates of Spring and Fall GWS are based on GSE measurements regularly  
21 made by San Luis Obispo County Department of Public Works (SLO DPW), NCSO, USGS, and  
22 Woodlands. The integration of GSE data is accomplished by using computer software to  
23 interpolate between measurements and calculate GWS within the principal production aquifer.  
24 Limited measurements of GSE were available for the years 1982, 1983, 1984, 1994 and 1997,  
25 precluding a reliable estimate of GWS for those years.

26 The amount of GWS under the Nipomo Mesa Management Area (NMMA) was computed  
27 by multiplying the saturated volume above sea level with the aerielly weighted specific yield  
28 (DWR, 2002), excluding bedrock (Figure 11: Base of Potential Water-Bearing Sediments,  
29 presented in the report, Water Resources of the Arroyo Grande - Nipomo Mesa Area [DWR  
30 2002]). The amount of GWS under the NMMA was constrained to the boundary determined in  
31 Phase III of the trial.

32 Data provided by DWR, consisting of well completion reports, lithographic logs,  
33 electronic logs, and pump tests, were used to develop an understanding of the hydrogeologic  
34 conditions underlying the NMMA. A systematic review of these data pertaining to wells used

1 for storage calculations was conducted in order to verify that each well's screened interval is  
2 within the principal production aquifer (Paso Robles Formation).

### 3 **Groundwater Surface Elevation Measurements**

4 Groundwater surface elevation data were obtained from SLO DPW, NCSO, USGS, and  
5 Woodlands (Table 2). SLO DPW measures GSE in monitoring wells during the spring and the  
6 fall of each year. Woodlands and NCSO measures GSE in their monitoring wells monthly. For  
7 the years 1975 to 1999, available representative GSE data were used to estimate GWS. For the  
8 years 2000 to 2008, only GSE data from wells in the proposed Hydrologic Monitoring Program  
9 were used to estimate GWS.

10 The GSE data was reviewed in combination with well completion reports and historical  
11 hydrographic records in order to exclude measurements that do not accurately represent static  
12 water levels within the principal production aquifer. Wells that do not access the principal  
13 production aquifer or were otherwise determined to not accurately represent static water levels  
14 within the aquifer were not included in analysis.

### 15 **Groundwater Surface Interpolation**

16 The individual GSE measurements from each year were used to produce a GSE field by  
17 interpolation using the inverse distance weighting (IDW) method.

### 18 **Groundwater Volume Estimate**

19 The amount of groundwater in storage under the Nipomo Mesa was estimated for the  
20 boundary determined in Phase III of the trial. The GWS was estimated by subtracting both the  
21 mean sea level surface (elevation equals zero) and the volume of bedrock above sea level from  
22 the saturated volume. The bedrock surface elevation is based on Figure 11: Base of Potential  
23 Water-Bearing Sediments, presented in the report, Water Resources of the Arroyo Grande -  
24 Nipomo Mesa Area (DWR 2002). The bedrock surface elevation was preliminarily verified by  
25 reviewing driller reports obtained from DWR. The saturated volume above sea level was  
26 multiplied by a specific yield of 11.7% to estimate the recoverable amount of GWS. The specific  
27 yield is based on the average weighted specific yield for the Nipomo Mesa Hydrologic Sub-  
28 Area (DWR 2002, pg. 86).
